① Introduction

② Factor Models

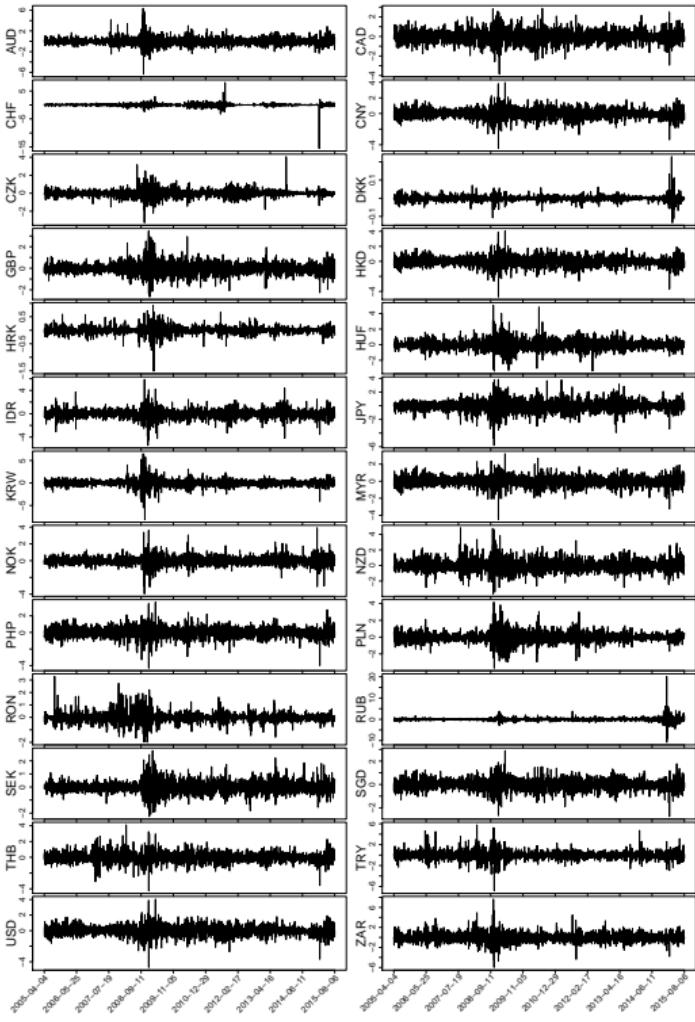

③ Application I

④ Sparse Factor Models

⑤ Application II

⑥ Estimation

⑦ Summary

## The univariate SV model

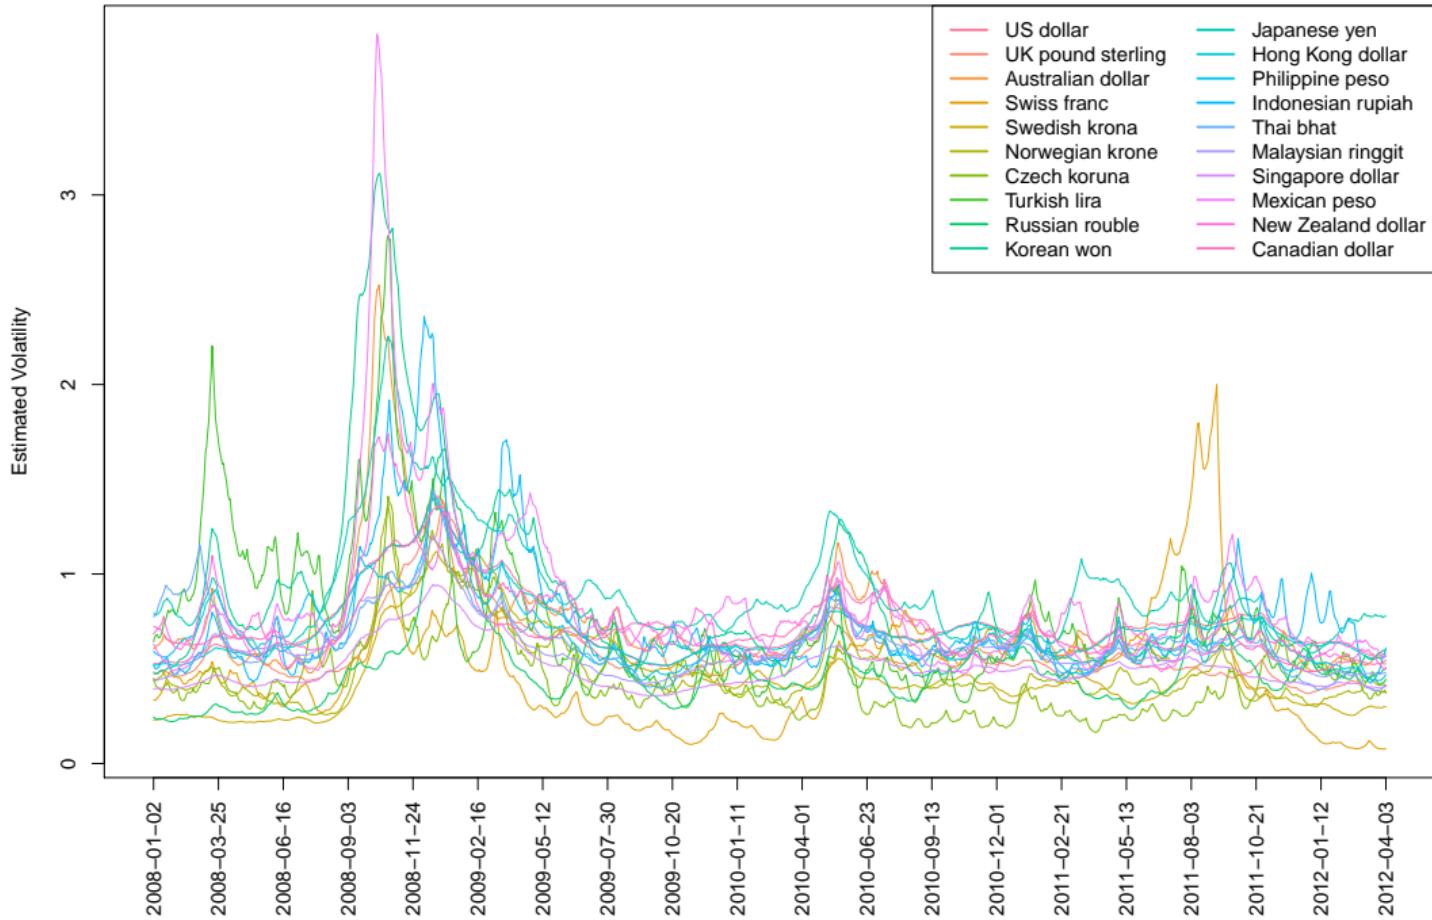

“Centered” version (e.g. Jacquier et al., 1994; Kim et al., 1998):

$$\begin{aligned}y_t &= e^{h_t/2} \varepsilon_t, & \varepsilon_t &\sim \mathcal{N}(0, 1), \\h_t &= \mu + \phi(h_{t-1} - \mu) + \sigma \eta_t, & \eta_t &\sim \mathcal{N}(0, 1),\end{aligned}$$

with  $\mathbf{h} = (h_0, \dots, h_T)$ ,  $\mu$ ,  $\phi$  and  $\sigma$  unknown. **Features:**

- > have separate error terms for the mean and volatility equations (**state space models**).
- > arise as discrete approximations to various diffusion processes in continuous-time asset pricing.
- > shares many “nice” properties with ( . . . )GARCH . . .
- > . . . while still showing important differences, e.g. a more realistic ACF of squared returns.
- > shows less/no remaining nonlinear dependencies in residuals (Jacquier et al., 1994).

# Individual SV models for daily EUR exchange rates (Kastner et al., 2014)

## Factor analysis recap

**Basic Static Factor Model:** Common factors  $\mathbf{f}_t = (f_{1t}, \dots, f_{rt})'$  are related to  $\mathbf{y}_t$  via

$$\mathbf{y}_t = \boldsymbol{\Lambda} \mathbf{f}_t + \boldsymbol{\varepsilon}_t, \quad \boldsymbol{\varepsilon}_t \sim \mathcal{N}_m(\mathbf{0}, \boldsymbol{\Sigma}),$$

where  $\boldsymbol{\Sigma} = \text{Diag}(\sigma_1^2, \dots, \sigma_m^2)$  and  $\boldsymbol{\Lambda}$  is the factor loading matrix.

Typically, orthogonal factors are used with  $\mathbf{f}_t \sim \mathcal{N}_r(\mathbf{0}, \mathbf{1}_r)$ . If furthermore  $\mathbf{f}_t$  and  $\boldsymbol{\varepsilon}_t$  are independent, we have

$$\mathbf{y}_t \sim \mathcal{N}_m(\mathbf{0}, \boldsymbol{\Omega}), \quad \boldsymbol{\Omega} = \boldsymbol{\Lambda} \boldsymbol{\Lambda}' + \boldsymbol{\Sigma}.$$

- > Factor models yield good estimators of the covariance  $\boldsymbol{\Omega}$  and (in particular) precision  $\boldsymbol{\Omega}^{-1}$  (Fan et al., 2008).
- > In econometrics, number of factors  $r \ll m$  (dimension of  $\mathbf{y}_t$ )  $\Rightarrow$  number of parameters grows linearly with  $m$ .
- > For (financial) time series, static factor models need to be extended to settings where variances and covariances change over time  $\Rightarrow$  combine factor models with SV models (Chib et al., 2006).

## Factor SV

Use  $m + r$  conditionally independent univariate SV models for  $h_{it}$ ,  $i = 1, \dots, m + r$ ,

$$h_{it} = \mu_i + \phi_i(h_{i,t-1} - \mu_i) + \sigma_i \eta_{it}, \quad \eta_{it} \sim \mathcal{N}(0, 1),$$

to define time-varying diagonal matrices

$$\boldsymbol{\Sigma}_t = \text{Diag}\left(e^{h_{1,t}}, \dots, e^{h_{m,t}}\right), \quad \mathbf{V}_t = \text{Diag}\left(e^{h_{m+1,t}}, \dots, e^{h_{m+r,t}}\right).$$

Model  $m$ -variate time series  $\mathbf{y}_t$  through the factor model:

$$\begin{aligned} \mathbf{f}_t &\sim \mathcal{N}_r(\mathbf{0}, \mathbf{V}_t), \\ \mathbf{y}_t &= \Lambda \mathbf{f}_t + \varepsilon_t, \quad \varepsilon_t \sim \mathcal{N}_m(\mathbf{0}, \boldsymbol{\Sigma}_t). \end{aligned}$$

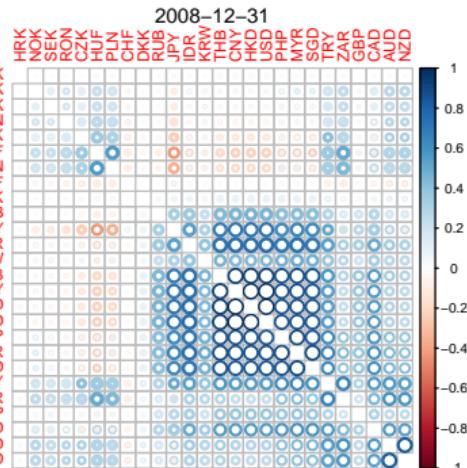

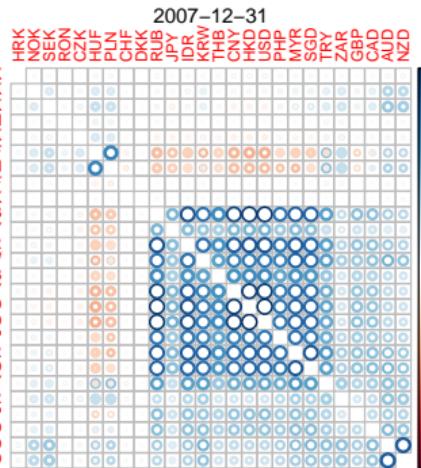

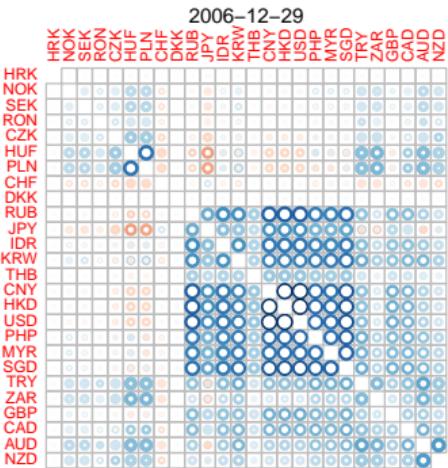

This yields a sparse representation of a time-varying covariance matrix  $\boldsymbol{\Omega}_t$ :

$$\mathbf{y}_t | \mathbf{h}_t \sim \mathcal{N}_m(\mathbf{0}, \boldsymbol{\Omega}_t(\mathbf{h}_t)), \quad \boldsymbol{\Omega}_t(\mathbf{h}_t) = \Lambda \mathbf{V}_t(\mathbf{h}_t) \Lambda' + \boldsymbol{\Sigma}_t(\mathbf{h}_t).$$

- > Conditionally,  $\mathbf{y}_t$  exhibits heteroskedasticity in many dimensions w/o their “curse”.
- > Marginally,  $\mathbf{y}_t$  follows a process with a fat tailed stationary distribution.

# Application to exchange rate data

Some posterior correlation matrices (mean  $\pm 2 \times \text{sd}$ ) [Video](#)

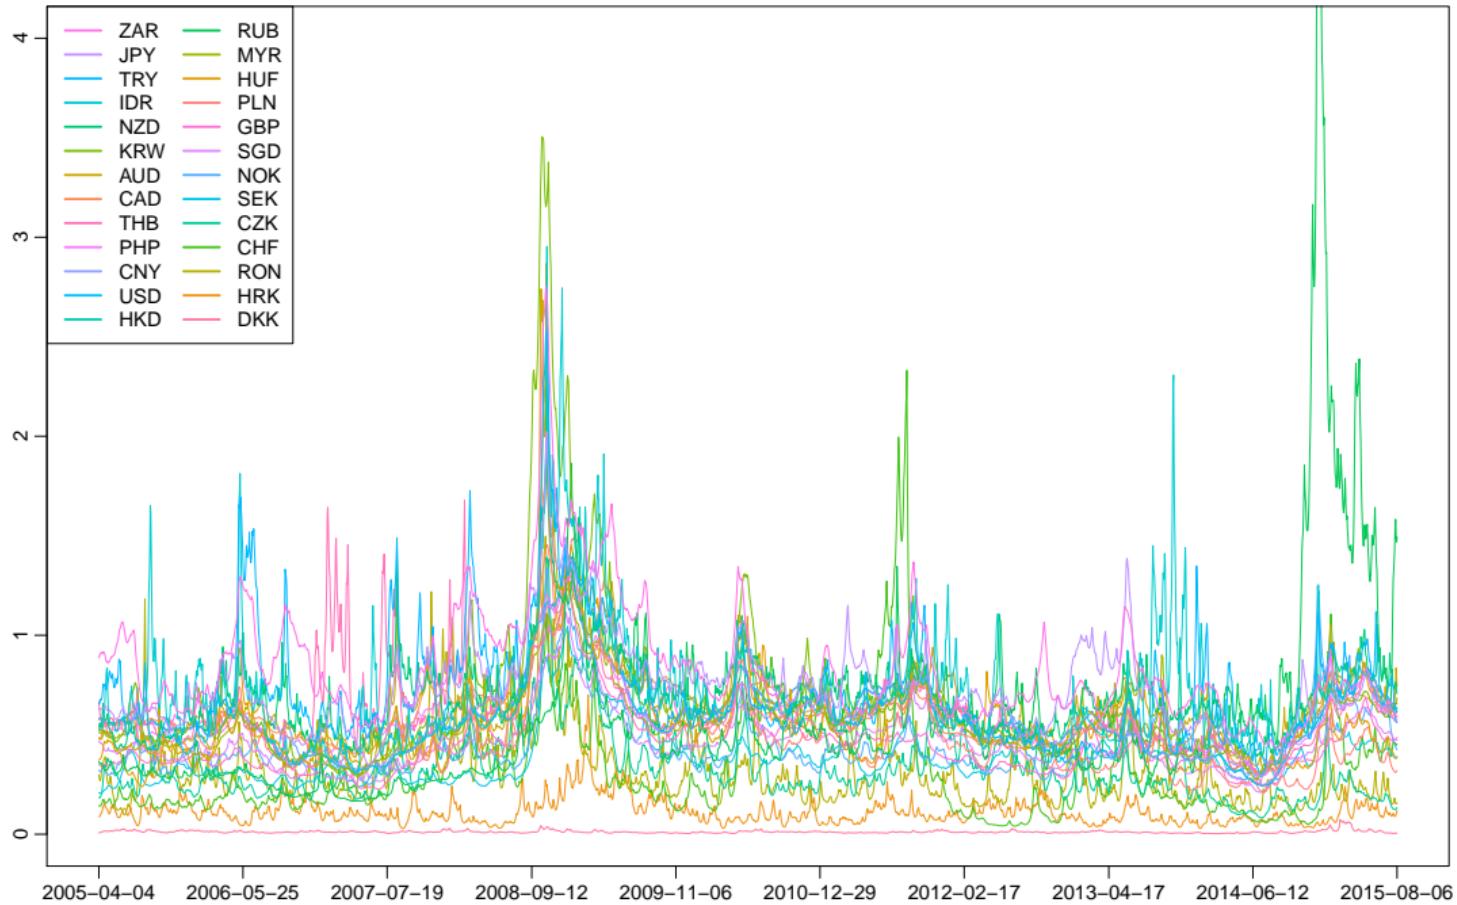

Quite some **additional sparsity** in terms of uncorrelated returns!

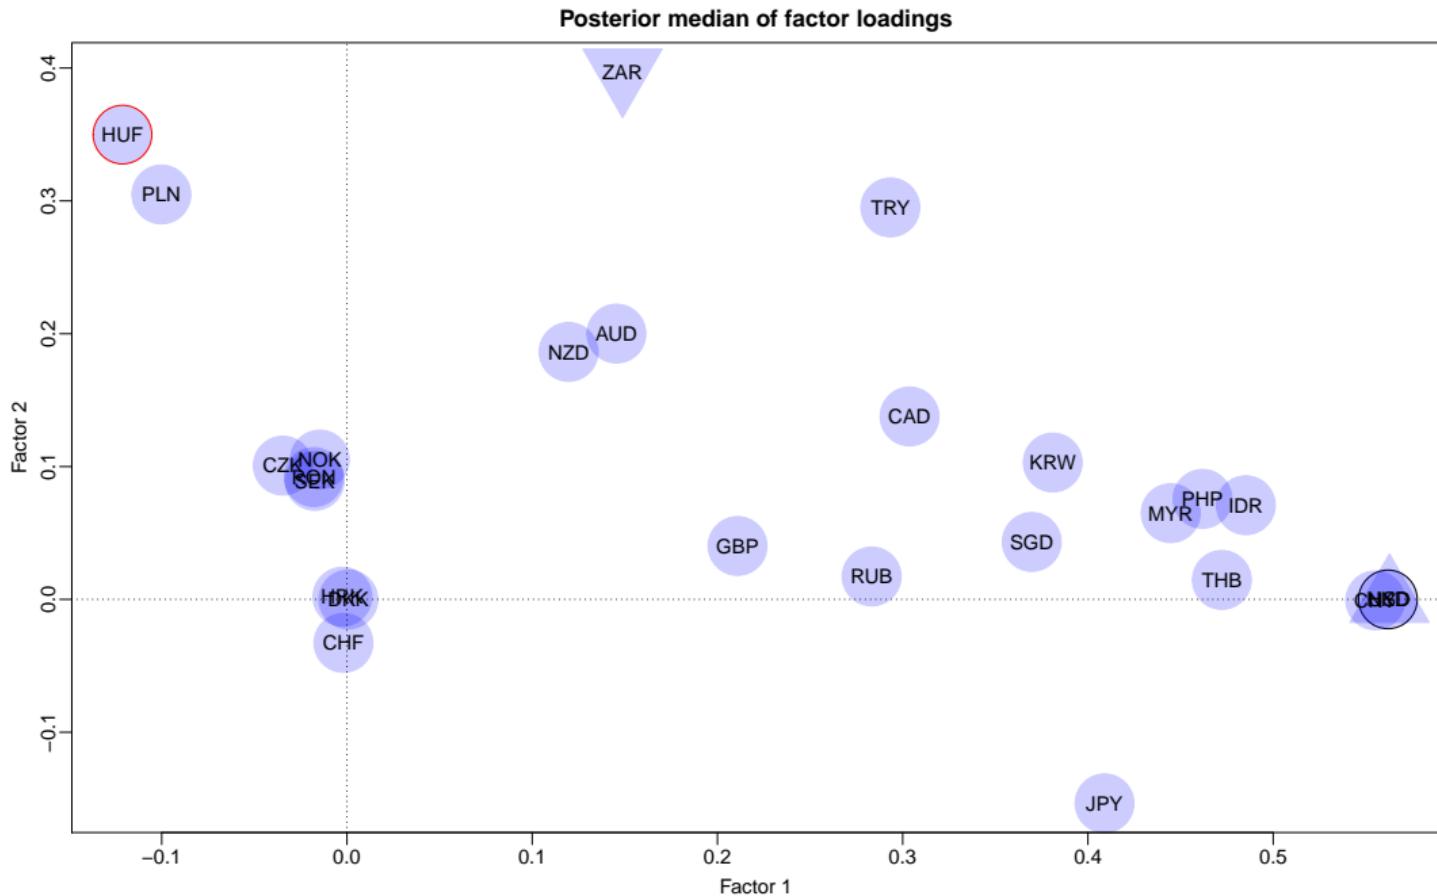

# Mean posterior correlations with USD

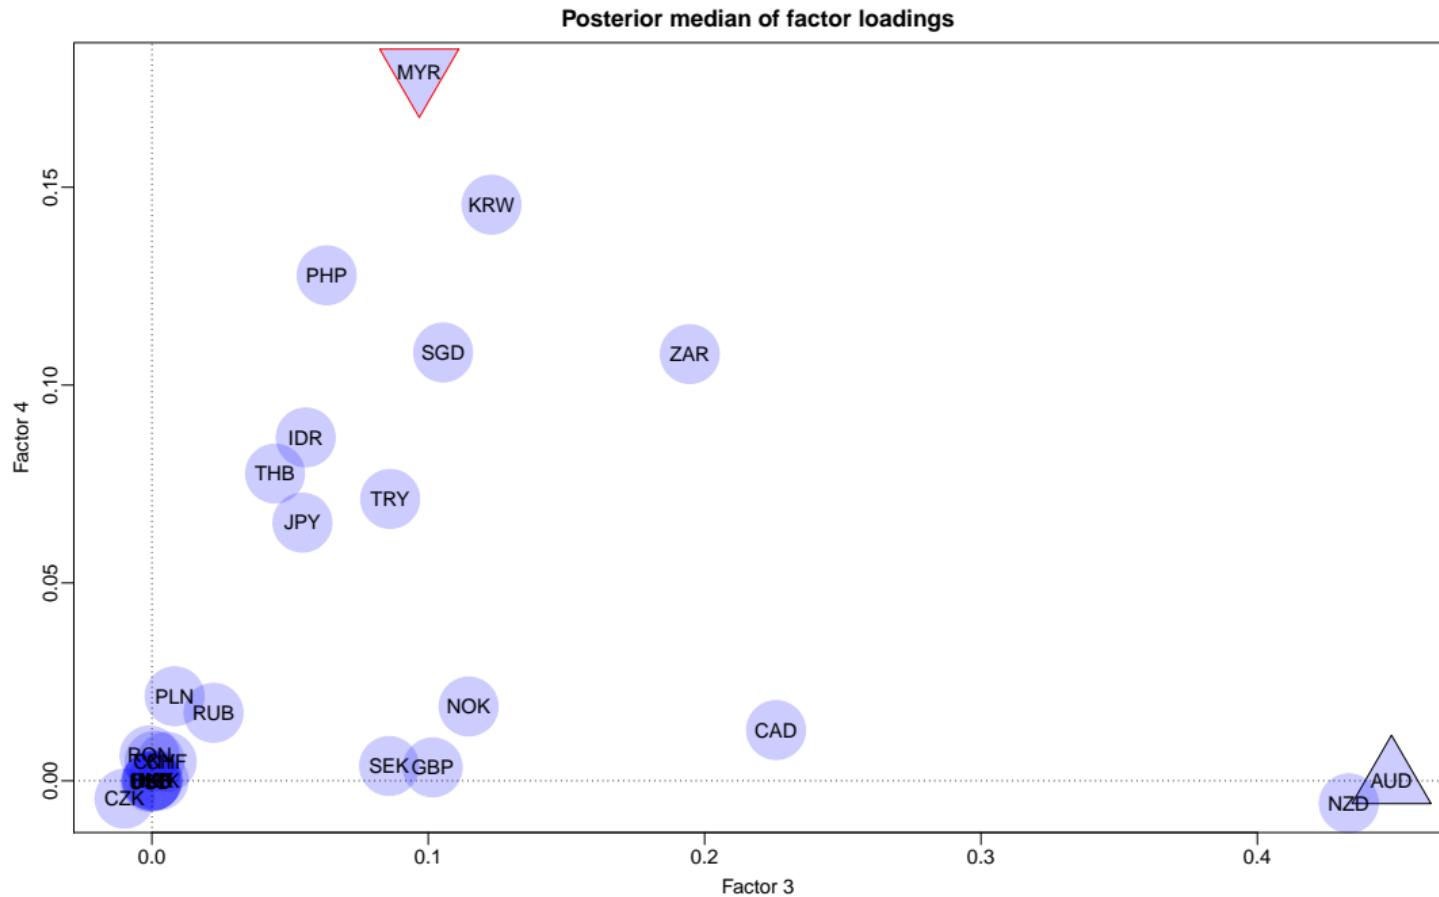

# Mean posterior volatilities

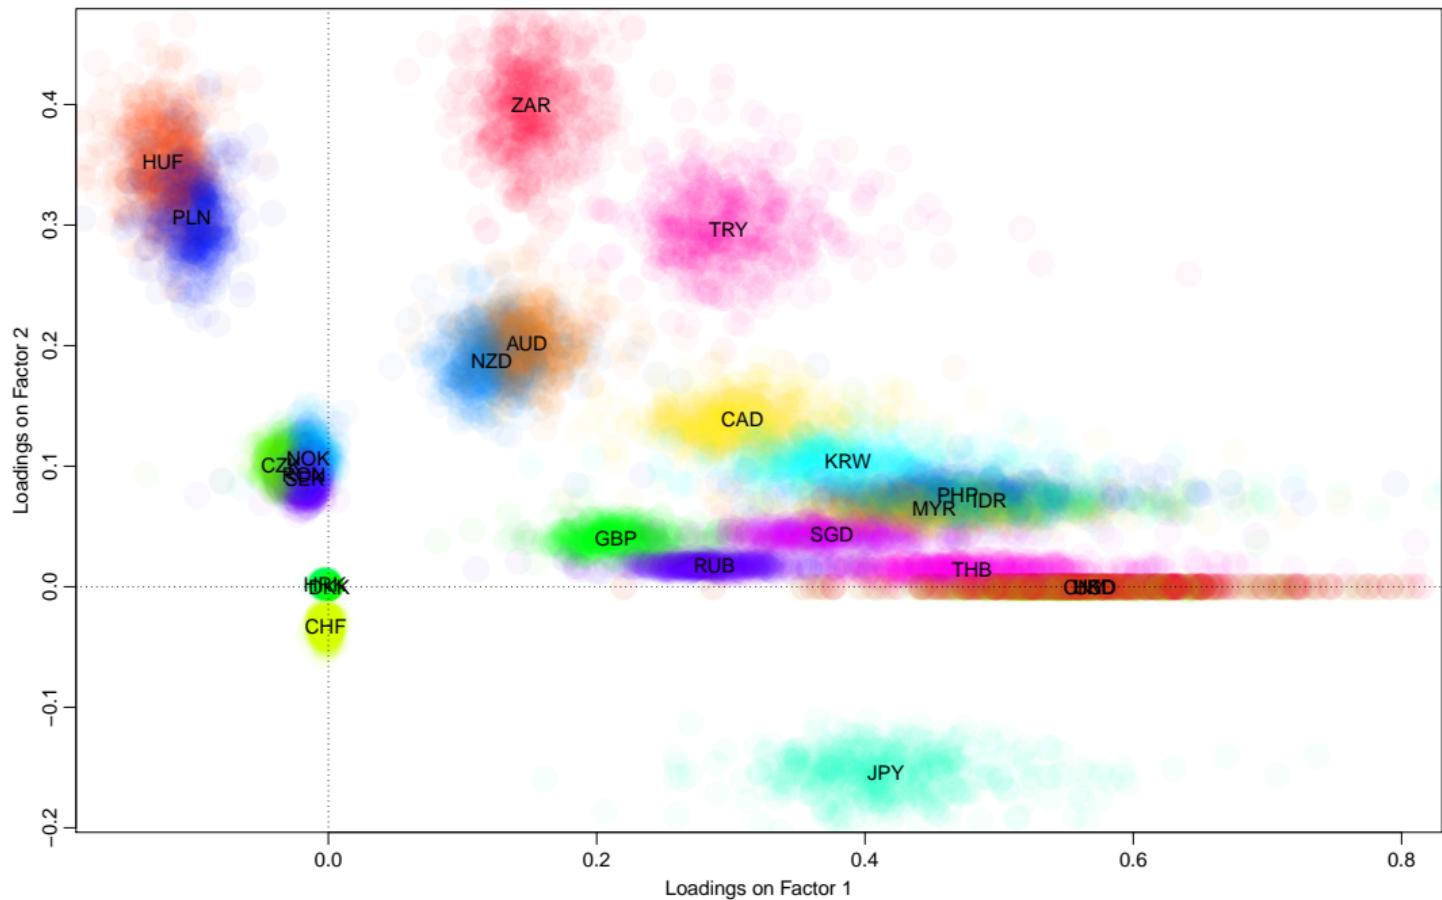

# Median of loadings posterior $\Lambda|y$ (factors 1 and 2)

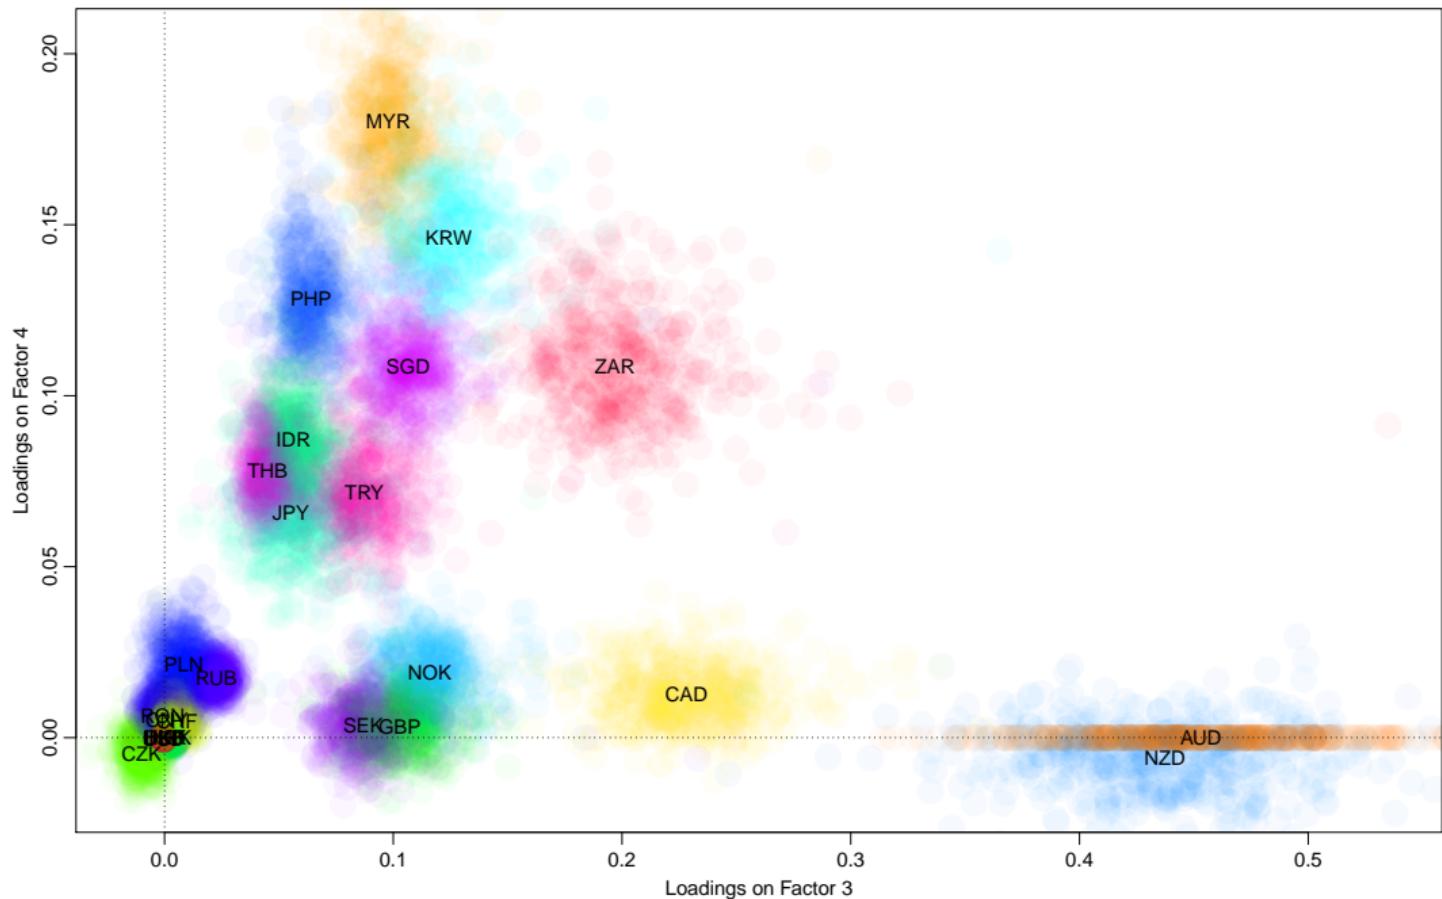

# Median of loadings posterior $\Lambda|y$ (factors 3 and 4)

## Posterior loadings distribution $\Lambda|y$ (factors 1 and 2)

## Posterior loadings distribution $\Lambda|y$ (factors 3 and 4)

## Sparse factor models

Factor models are a sparse representation of  $\Omega$  and  $\Omega^{-1}$ . To achieve additional sparsity, use shrinkage priors a.k.a. penalized likelihood.

- > Point mass priors
  - > Basic factor model (West, 2003; Carvalho et al., 2008; Frühwirth-Schnatter and Lopes, 2015)
  - > Bayesian dedicated factor analysis (Conti et al., 2014)
  - > Sparse dynamic factor models (Kaufmann and Schumacher, 2013)
- > Continuous shrinkage priors, e.g. in sparse Bayesian infinite factor models (Bhattacharya and Dunson, 2011)
- > Latent thresholding approaches (Nakajima and West, 2013; Zhou et al., 2014)
- > ...

## Sparse SV factor models

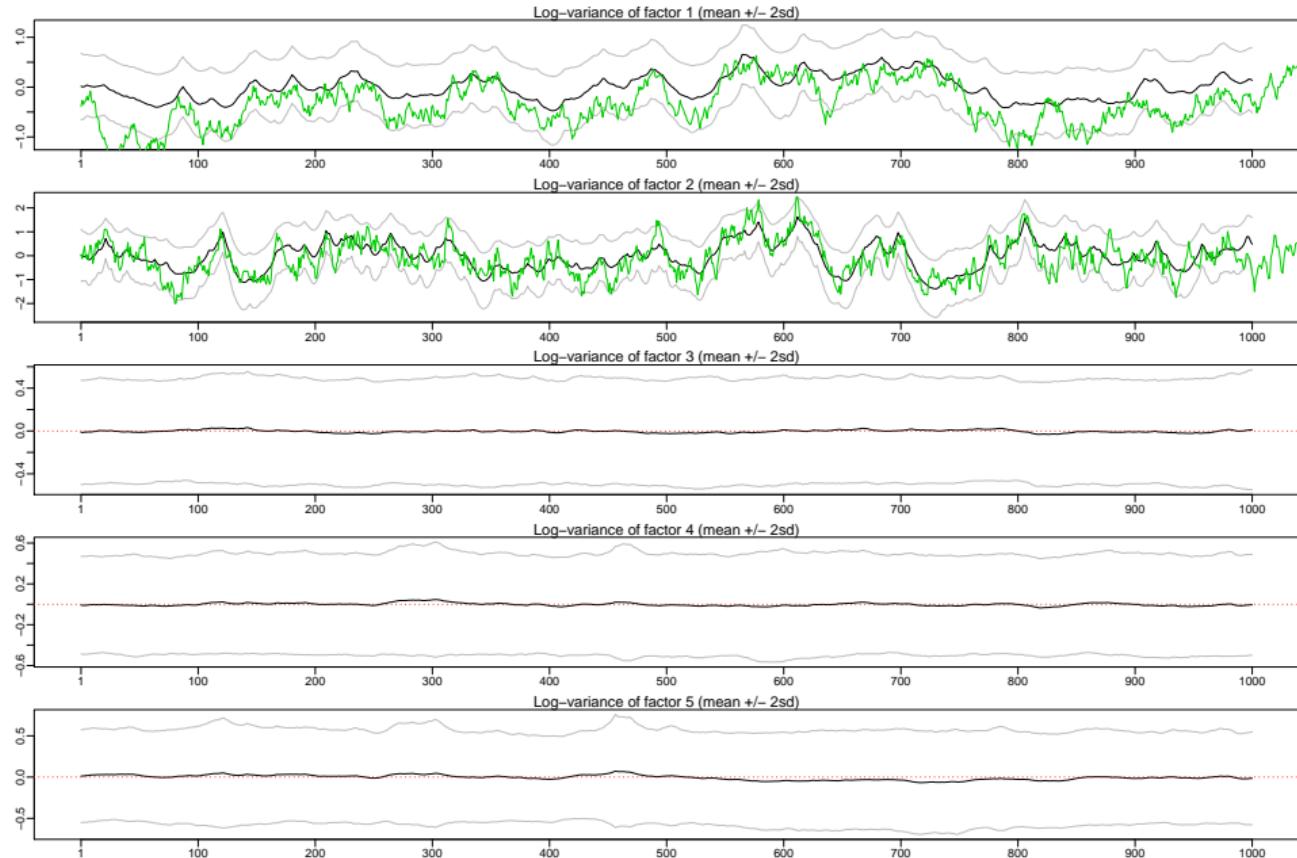

Use continuous shrinkage priors such as the **Normal-Gamma prior** (Griffin and Brown, 2010):

$$\Lambda_{ij} | \lambda_j, \tau_{ij} \sim \mathcal{N}\left(0, \tau_{ij}^2 / \lambda_j^2\right), \quad \lambda_j^2 \sim \mathcal{G}(c, d), \quad \tau_{ij}^2 \sim \mathcal{G}(a, a).$$

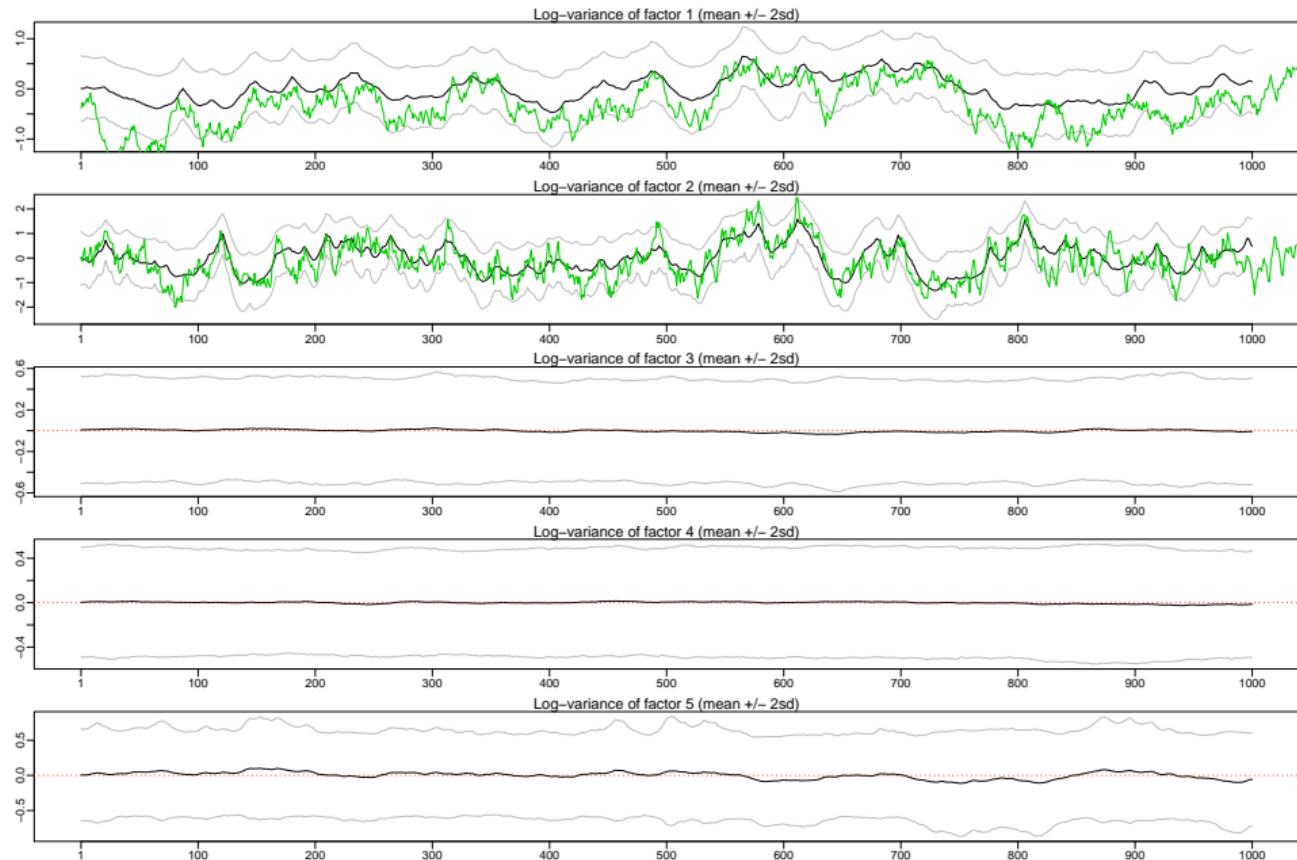

Visualization

- >  $\mathbb{V}(\Lambda_{ij} | \lambda_j^2) = 1/\lambda_j^2$ ,  $\mathbb{V}(\Lambda_{ij}) = d/(c - 1)$  if it exists
- > Excess kurtosis of  $\Lambda_{ij}$  is  $3/a$  if it exists
- > Shrink globally (column-wise) through  $\lambda_j^2$
- > Adjust locally (element-wise) through  $\tau_{ij}$ :  $\tau_{ij} < 1$  more,  $\tau_{ij} > 1$  less shrinkage
- > Bayesian Lasso (Park and Casella, 2008) arises for  $a = 1$

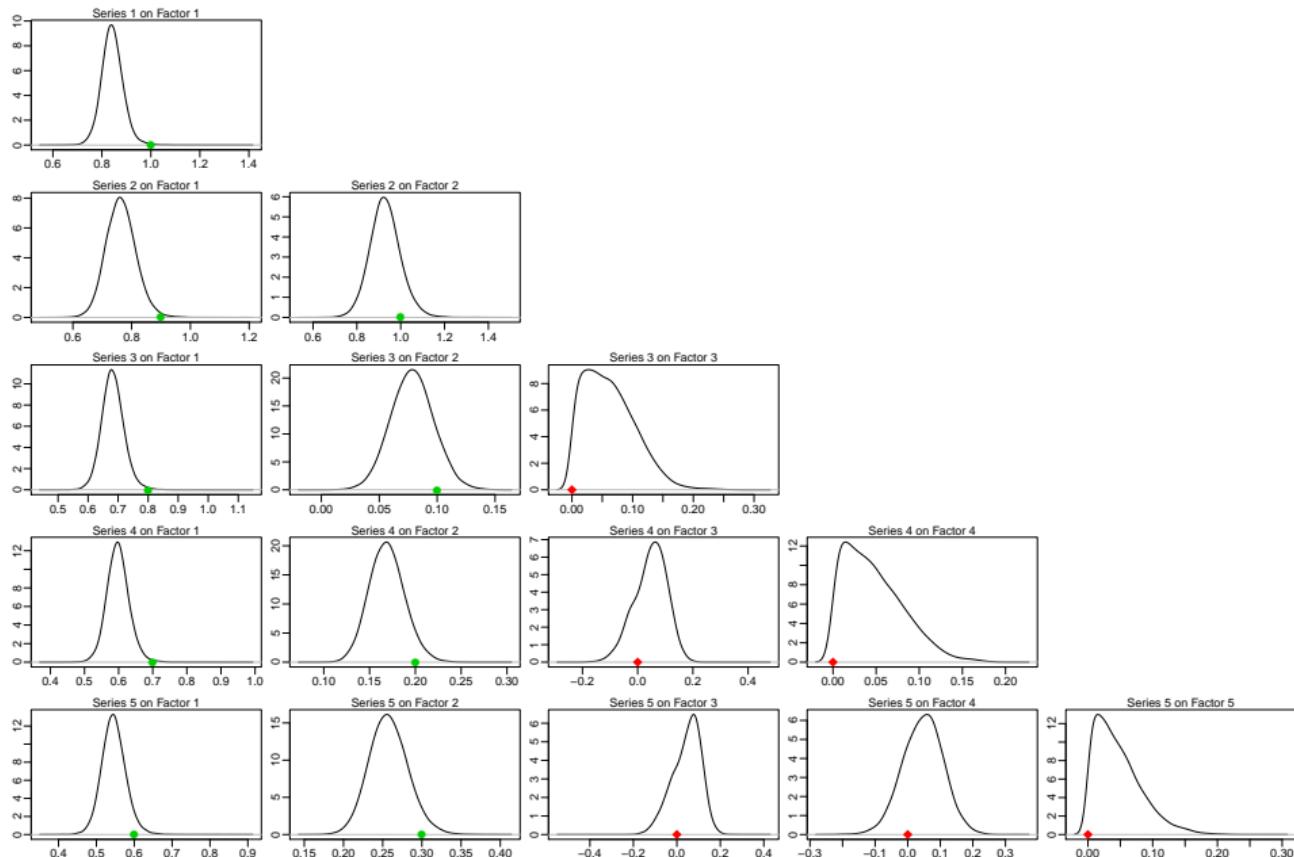

# Simulation: $r_{\text{true}} = 2$ , Normal prior ( $m = 10$ , $T = 1000$ )

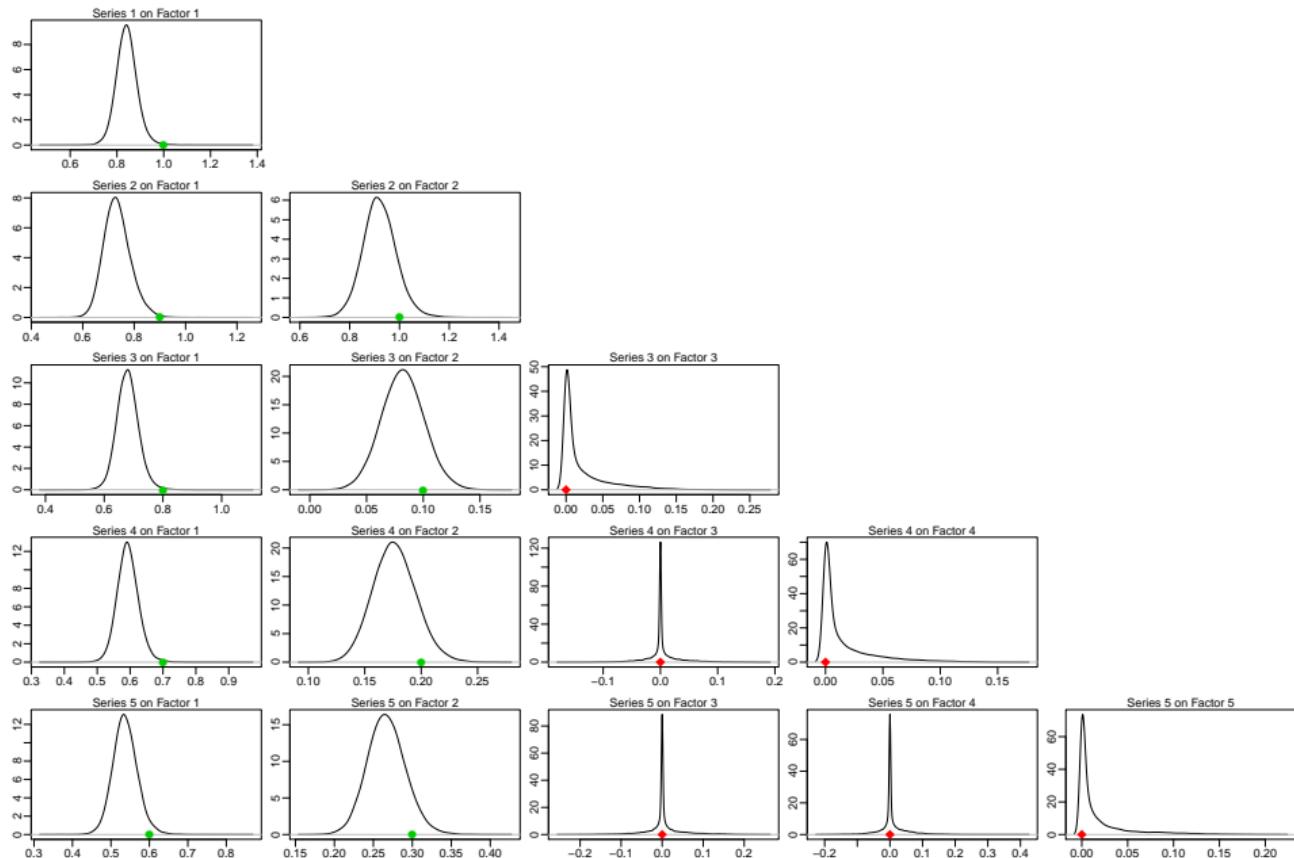

# Simulation: $r_{\text{true}} = 2$ , NG prior, ( $m = 10$ , $T = 1000$ )

# Simulation: $r_{\text{true}} = 2$ , Normal prior ( $m = 10$ , $T = 1000$ )

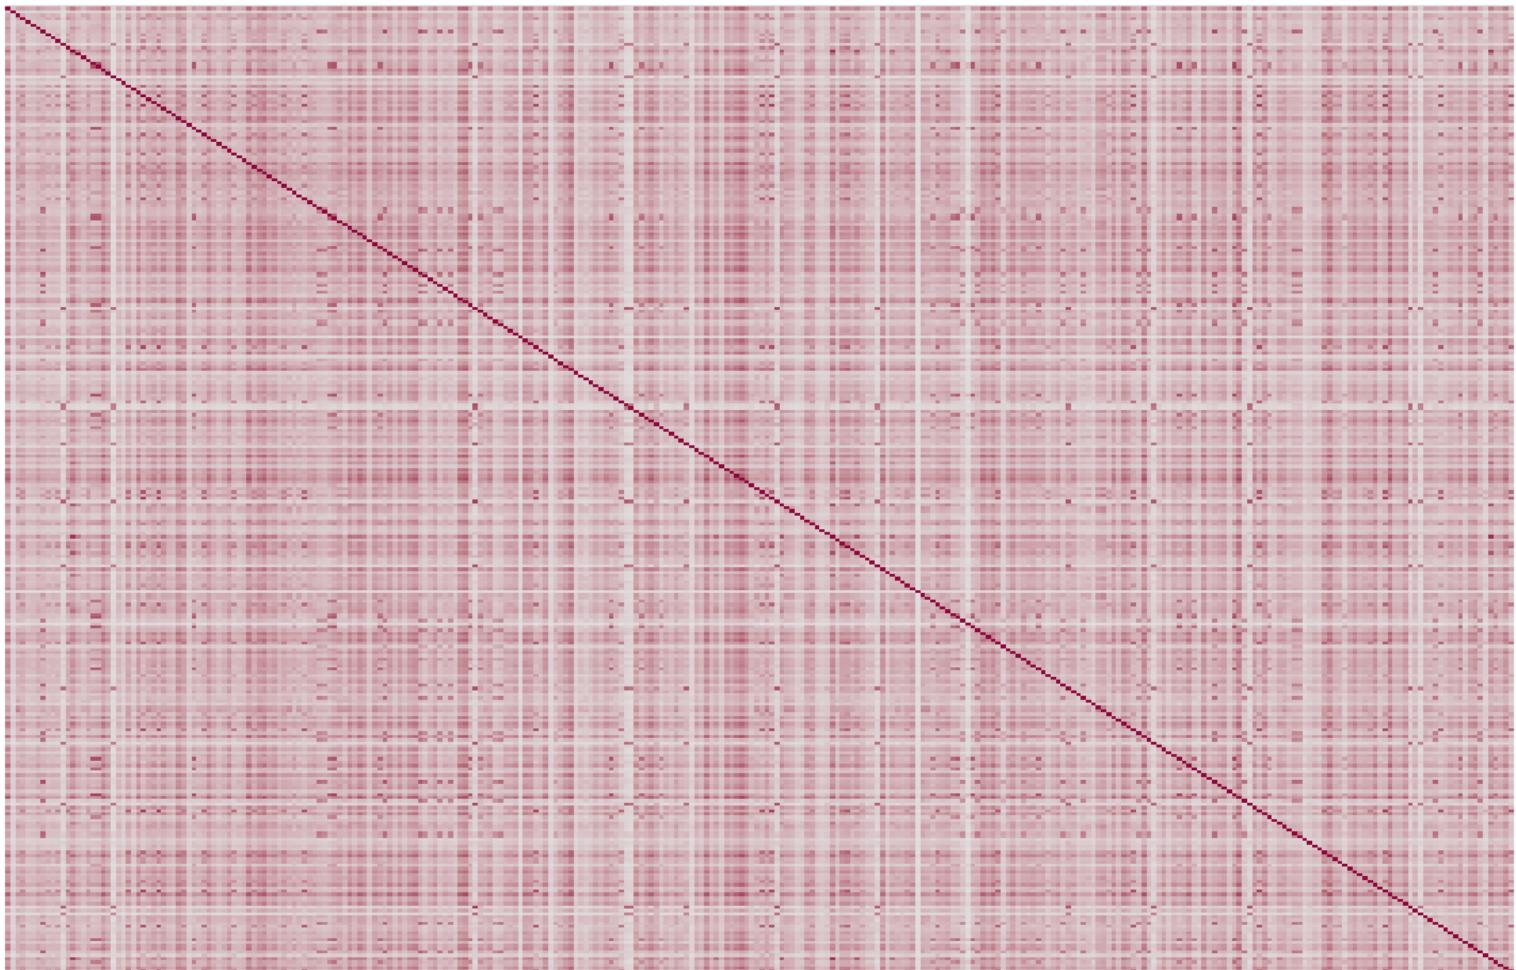

# Simulation: $r_{\text{true}} = 2$ , NG prior, ( $m = 10$ , $T = 1000$ )

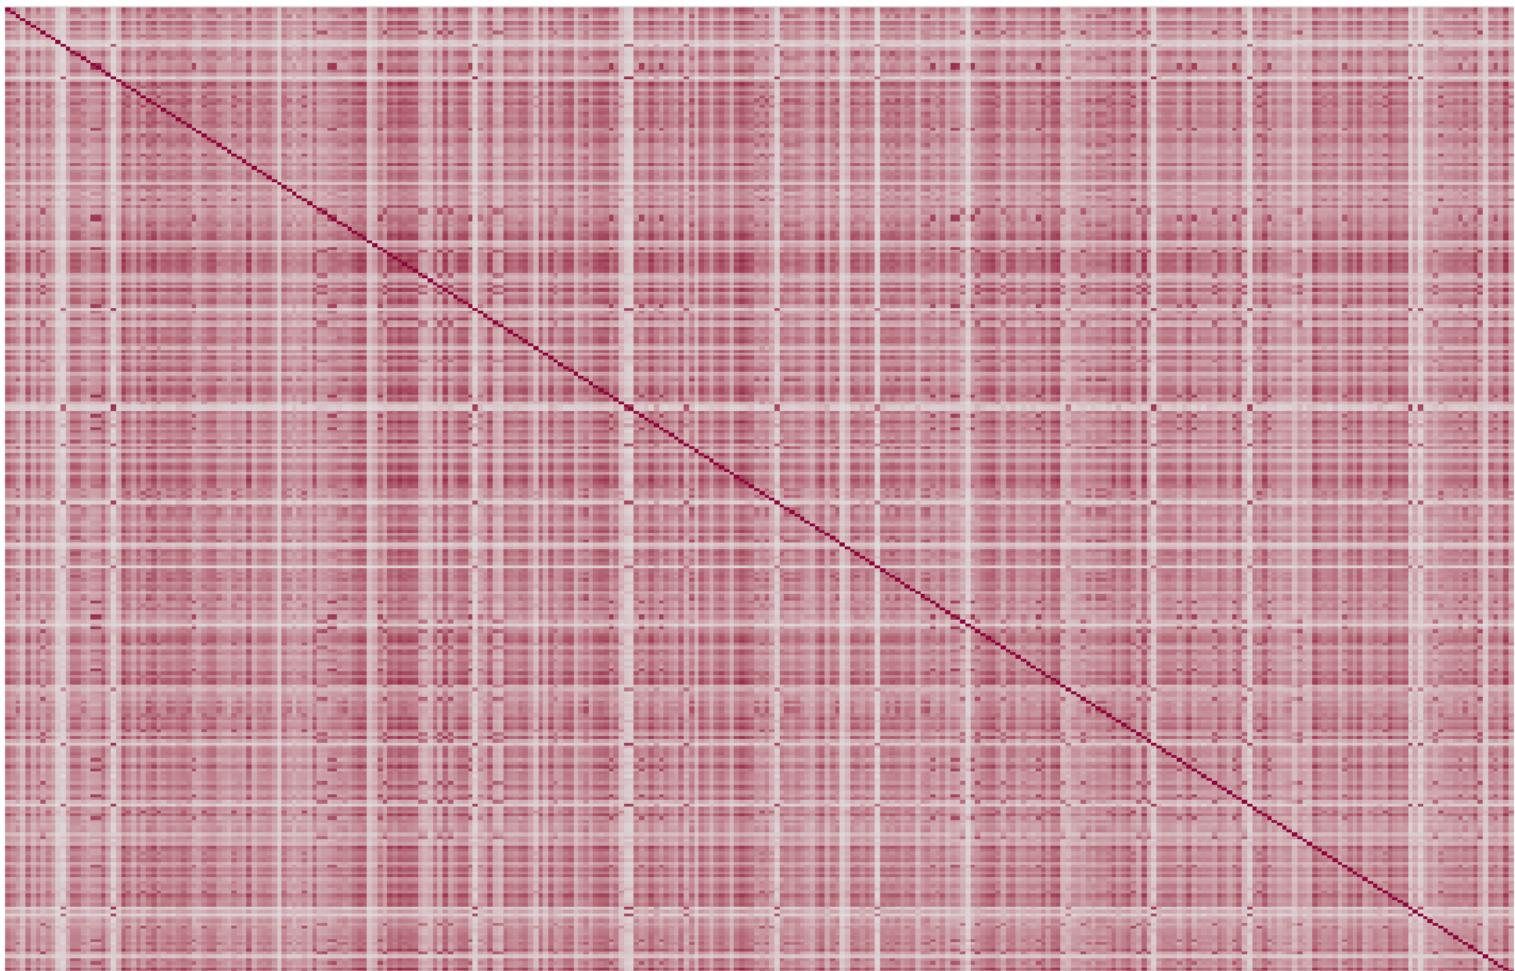

## Application to S&P 500 members

- > Seven-factor SV model to stock prices listed in the S&P 500 index.
- > Only firms which have been listed from November 1994 onwards, resulting in  $m = 300$  stock prices on 5001 days, ranging from 11/1/1994 to 12/31/2013.
- > Data was obtained from Bloomberg Terminal in January 2014.
- > Investigate  $T = 5000$  demeaned percentage log-returns.
- > Time-varying covariance matrix with 45150 elements on 5000 days can be well explained by 7 factors with many factor loadings shrunken to 0.

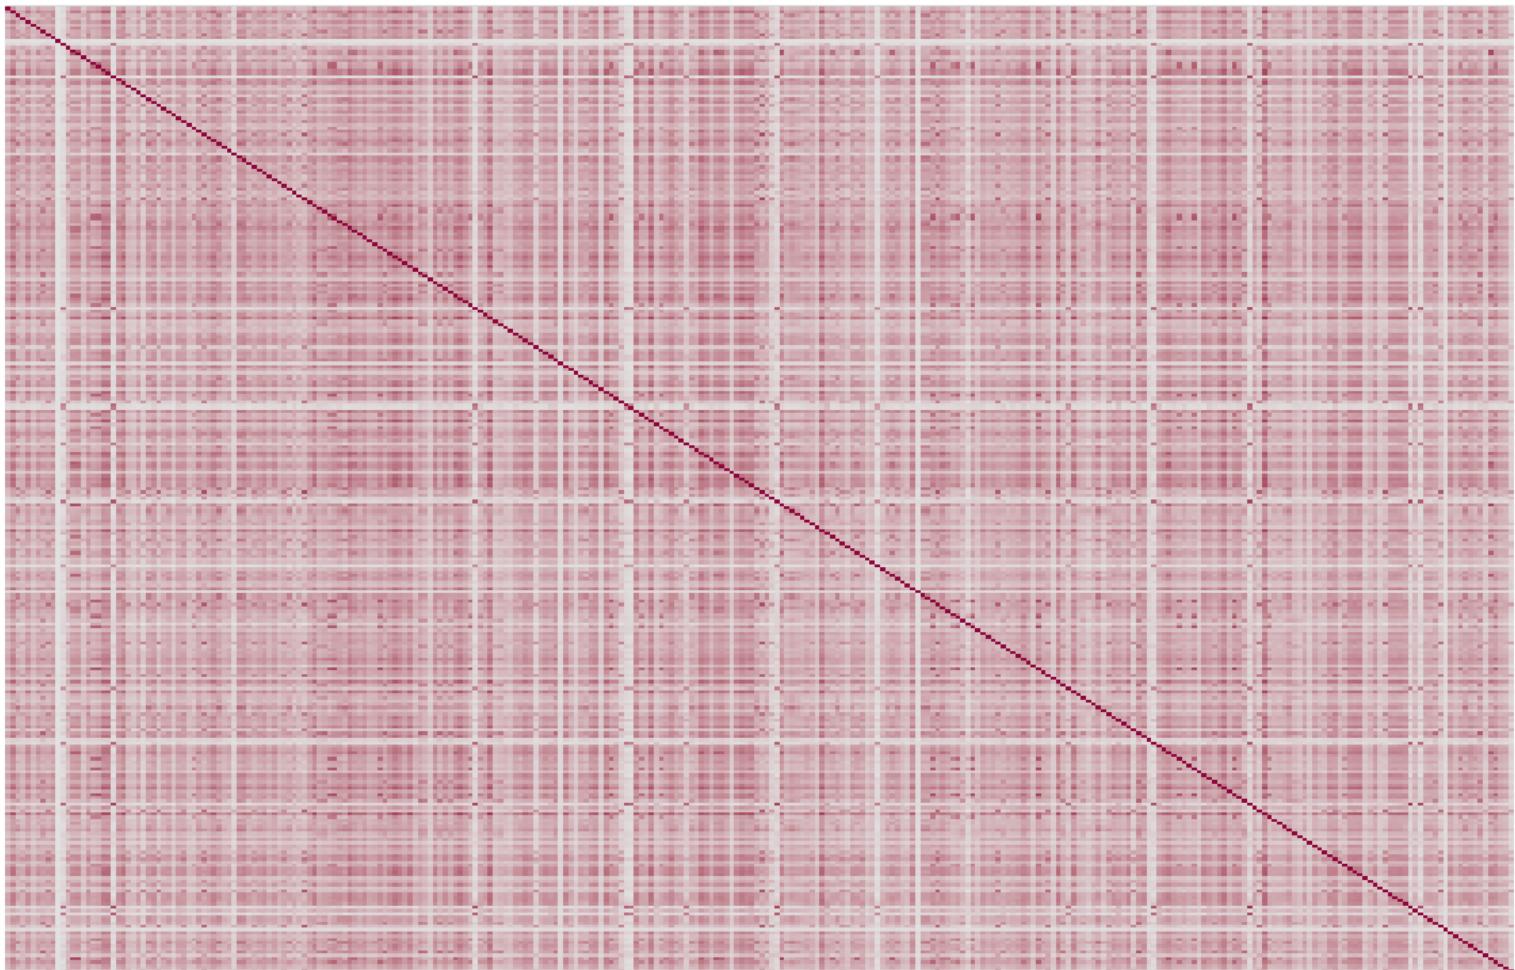

Median correlation matrix on 11/14/2007

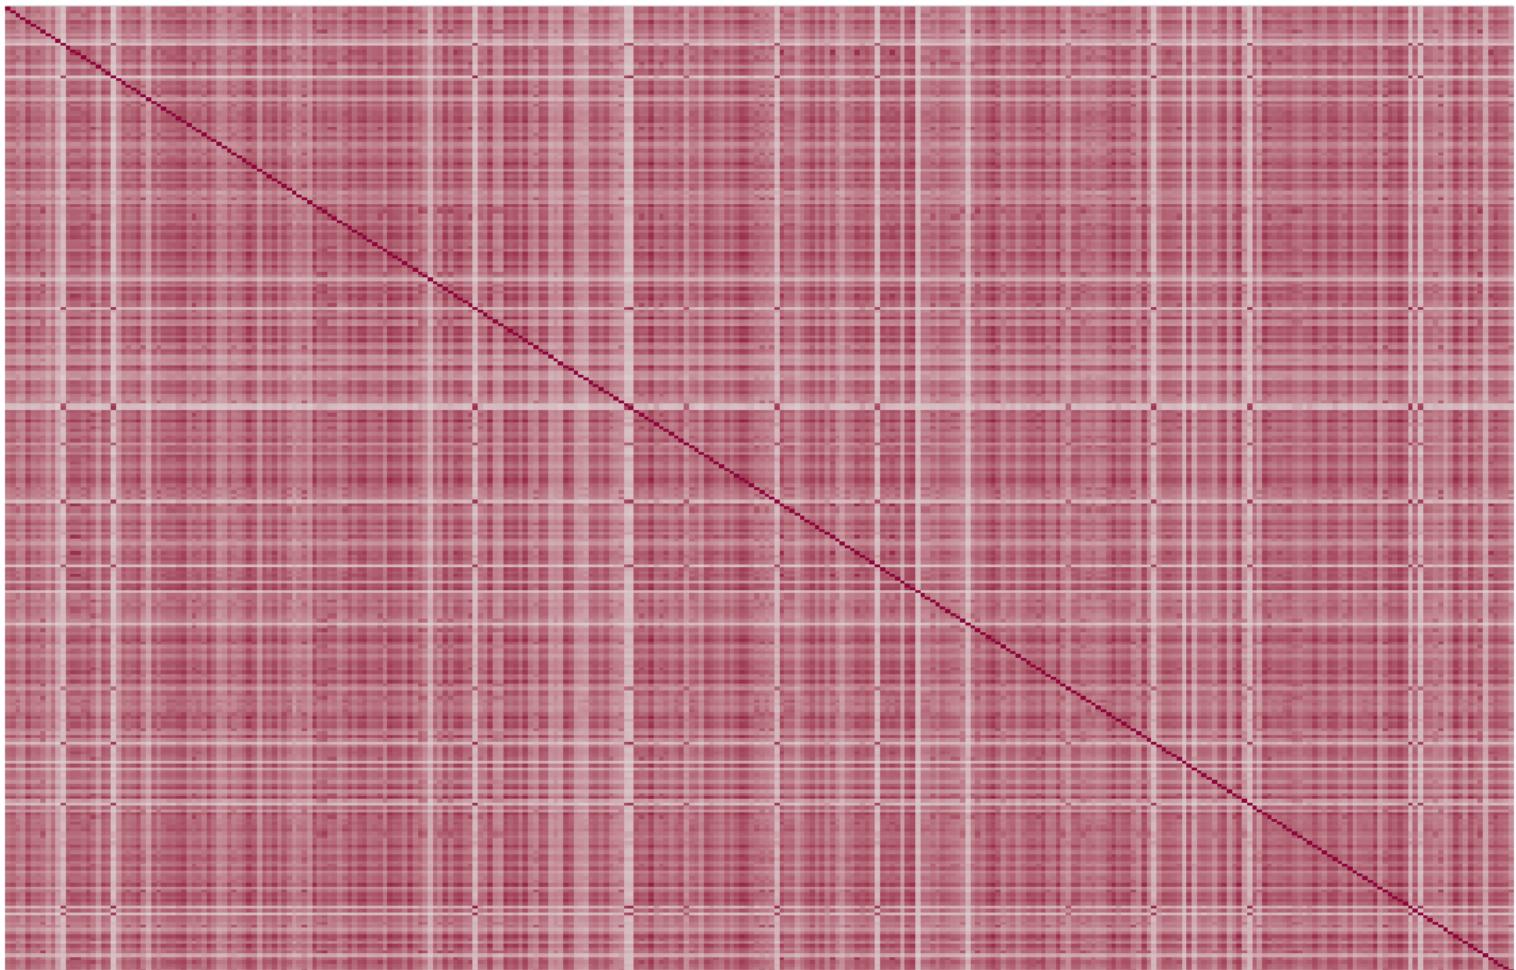

Median correlation matrix on 10/29/2008

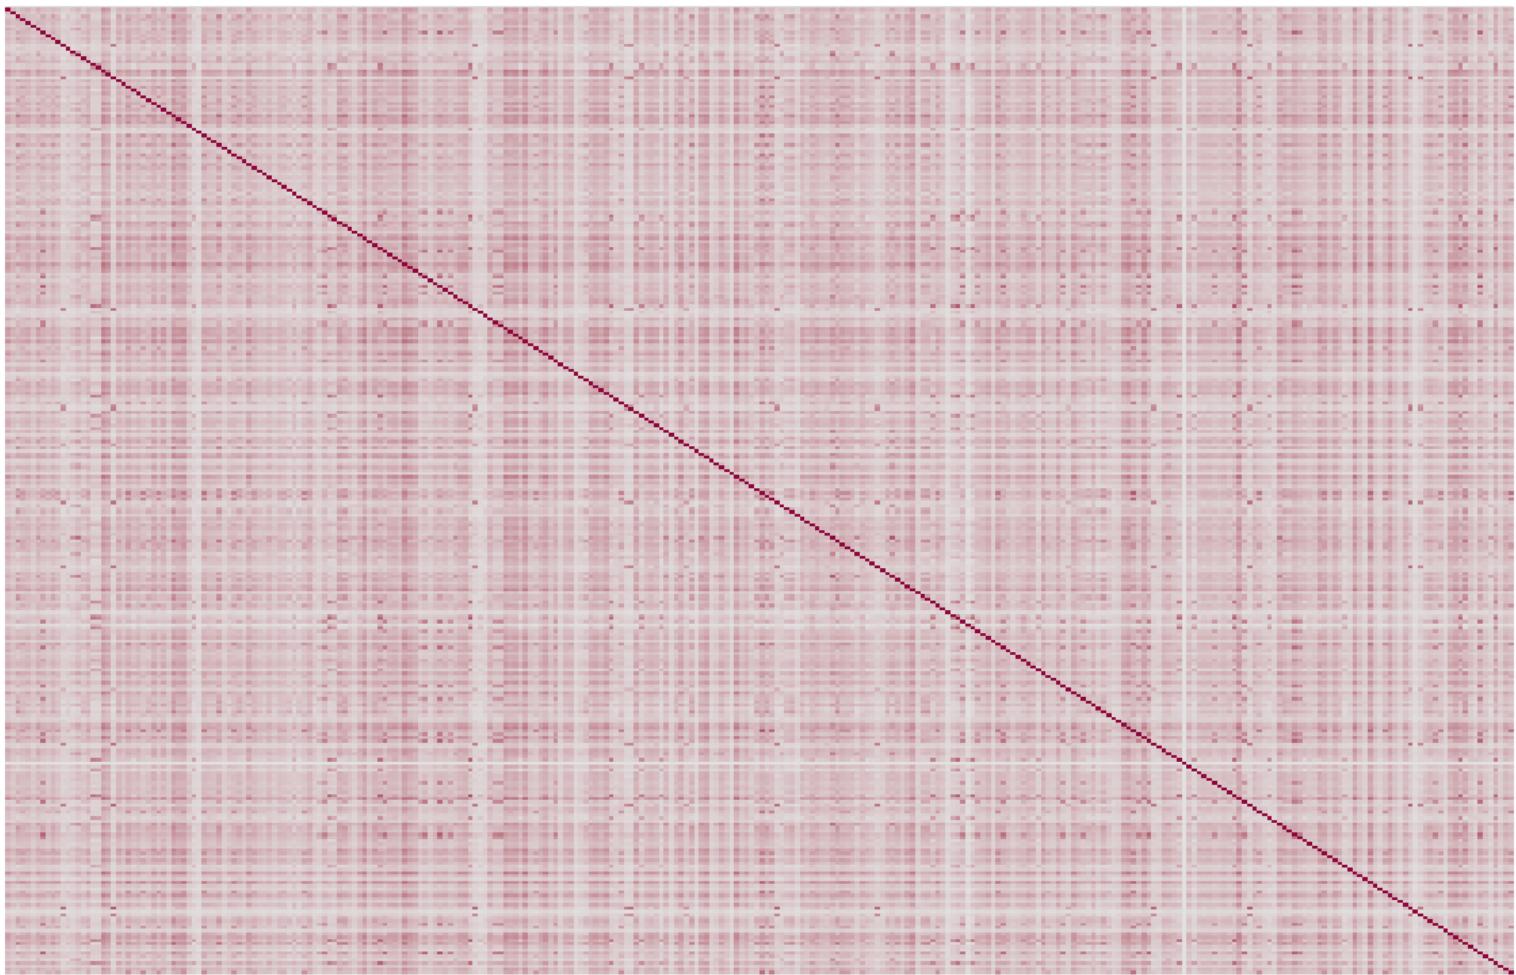

Median correlation matrix on 8/5/2009

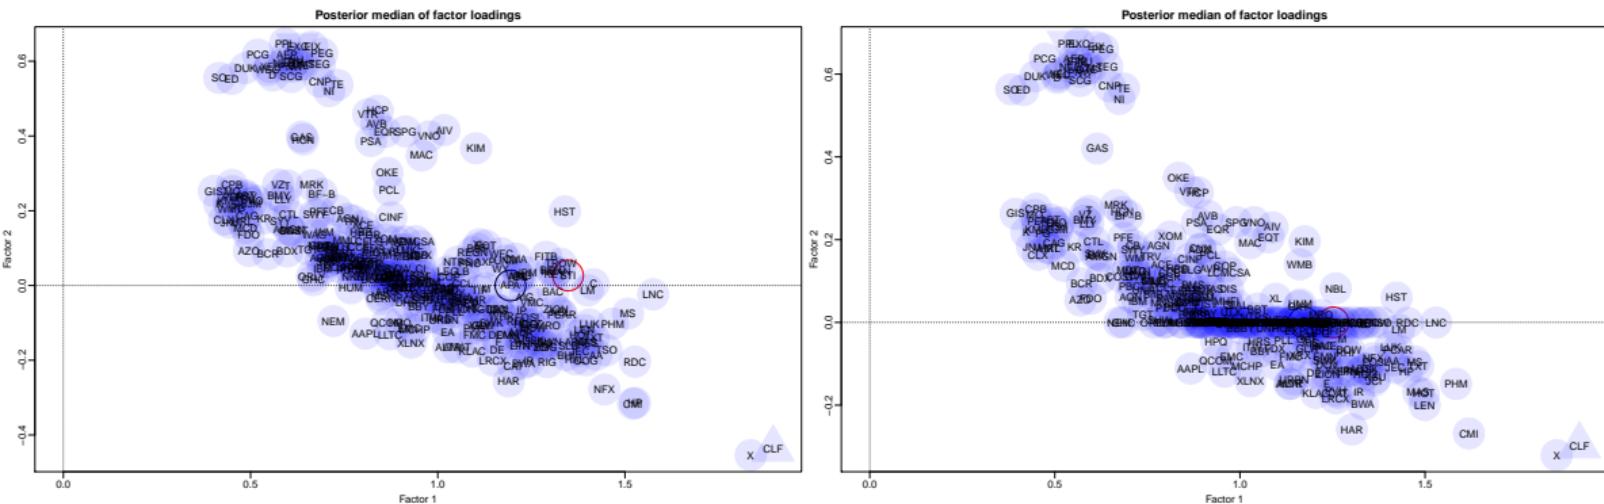

Median correlation matrix on 5/12/2010

Median correlation matrix on 4/27/2011

# S&P 500: Loadings on factors 1/2 (of 7), N prior (left) and NG prior (right)

## Practical implementation

Full conditional Gibbs sampling with efficient solutions for expensive or non-standard steps:

- > Sampling the prior scalings  $\tau_{ij}^2$  of the shrinkage prior: efficient adaptive rejection sampling (Hörmann and Leydold, 2013), implemented in R-Package **GIGrvg** (Leydold and Hörmann, 2014).
- > Sampling the univariate SVs: efficient auxiliary mixture sampling (Kastner and Frühwirth-Schnatter, 2014), implemented in R-Package **stochvol** (Kastner, forthcoming).
- > Everything in C/C++ using **Armadillo** (Sanderson, 2010) linked to R via **RcppArmadillo** (Eddelbuettel and Sanderson, 2014).

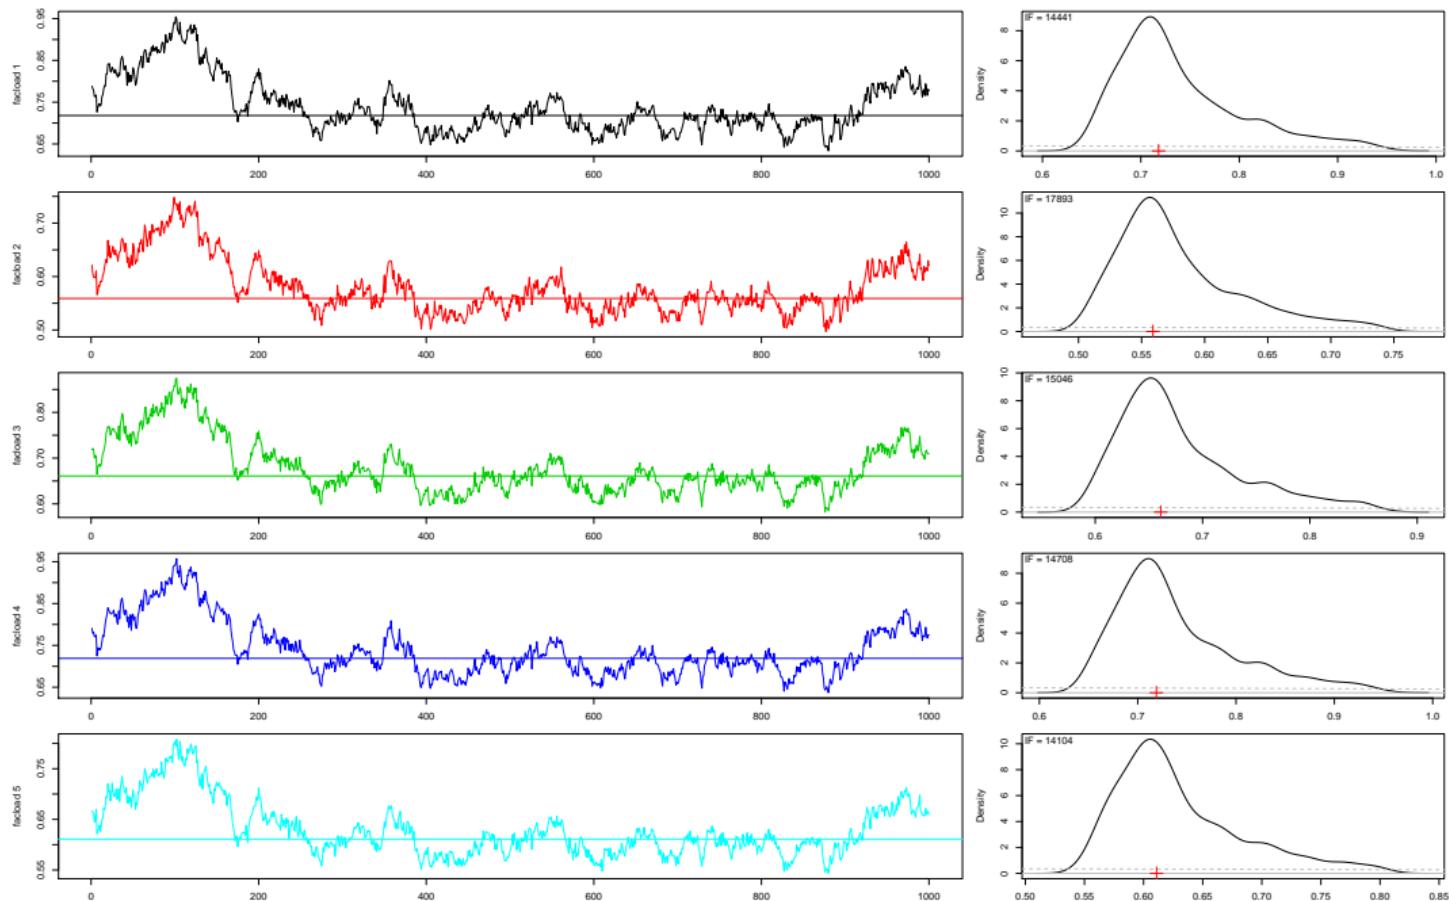

## Practical implementation

Full conditional Gibbs sampling with efficient solutions for expensive or non-standard steps:

- > Sampling the prior scalings  $\tau_{ij}^2$  of the shrinkage prior: efficient adaptive rejection sampling (Hörmann and Leydold, 2013), implemented in R-Package **GIGrvg** (Leydold and Hörmann, 2014).

- > Everything in C/C++ using **Armadillo** (Sanderson, 2010) linked to R via **RcppArmadillo** (Eddelbuettel and Sanderson, 2014).

However...

# Extreme mixing problems for simulated data (thinning of 100!)

## Boosting MCMC for state space models

Chib et al. (2006): no Gibbs sampling, MH-algorithm with sophisticated proposals to sample  $\Lambda$  without conditioning on  $f$ .

More general strategies:

- > **Parameterizations matter** for MCMC (Gelfand et al., 1995; Papaspiliopoulos et al., 2007), in particular for state space models – centered versus non-centered parameterizations (Frühwirth-Schnatter, 2004; Strickland et al., 2008).
- > **Marginal data augmentation** (van Dyk and Meng, 2001): move to a non-identified state space model through a working parameter (Frühwirth-Schnatter and Lopes, 2015; Conti et al., 2014).
- > **Ancillarity-sufficiency interweaving strategy (ASIS)** (Yu and Meng, 2011): move between parameterizations during sampling.

## Interweaving the factor loadings

Exploit non-identifiability of factor models to move between the three levels of the hierarchical latent state representation.

Baseline representation:

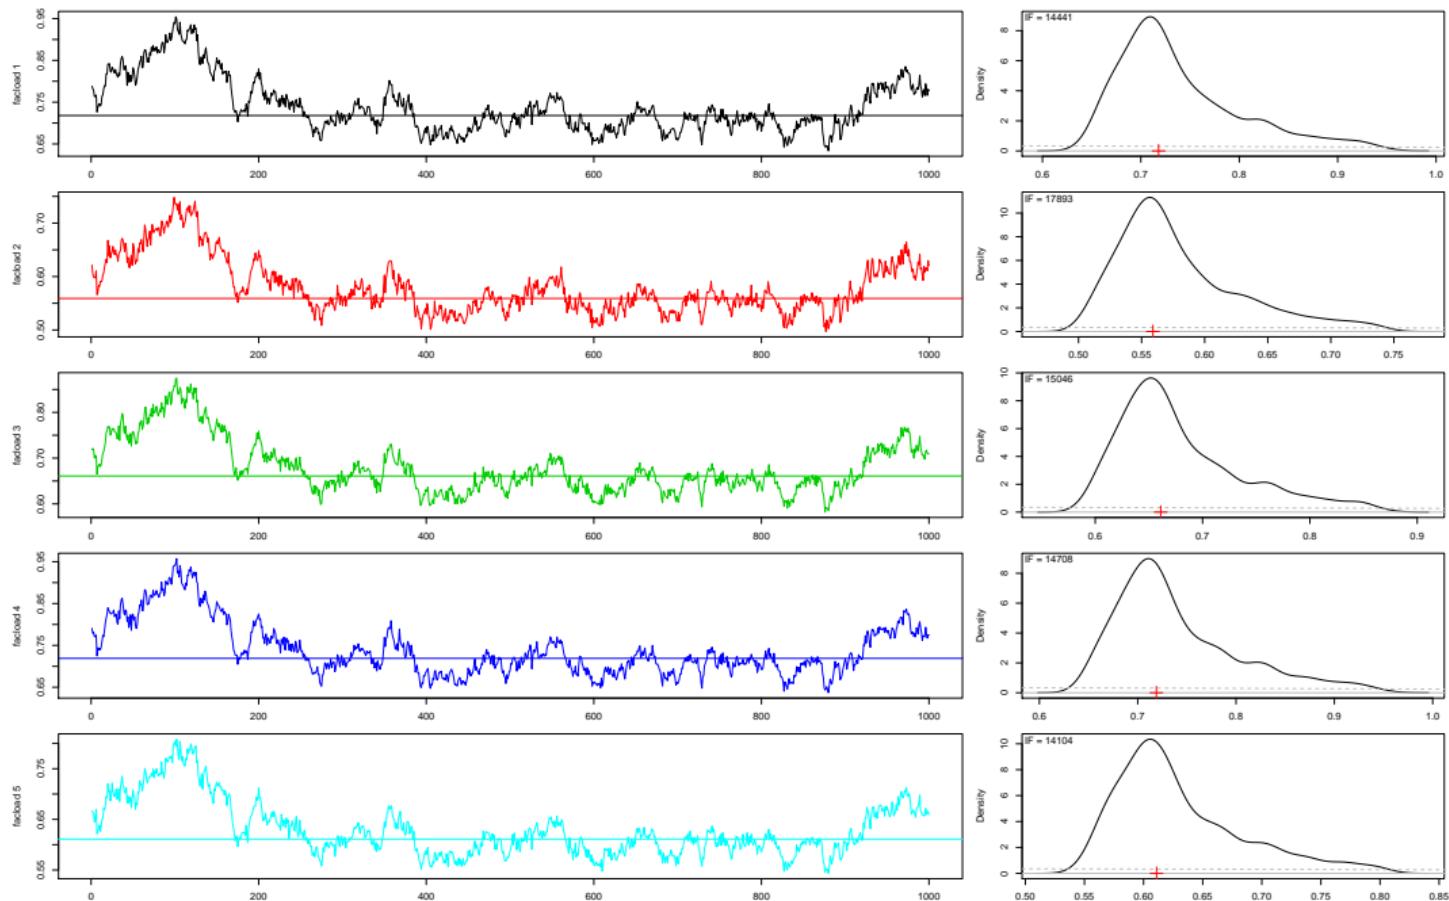

$$\mathbf{y}_t = \Lambda \mathbf{f}_t + \varepsilon_t,$$

with  $\Lambda_{ii} \neq 0$ ,  $i = 1, \dots, r$ , and

$$\begin{aligned} f_{it} &\sim \mathcal{N}(0, 1 \cdot e^{h_{m+i,t}}), \quad i = 1, \dots, r, \\ h_{m+i,t} &= \mu_{m+i} + \phi_{m+i}(h_{m+i,t} - \mu_{m+i}) + \eta_{m+i,t}, \end{aligned}$$

with  $\mu_{m+i} = 0$ .

# Extreme mixing problems for simulated data (thinning of 100!)

## Interweaving the factor loadings

Exploit non-identifiability of factor models to move between the three levels of the hierarchical latent state representation.

Shallow interweaving representation:

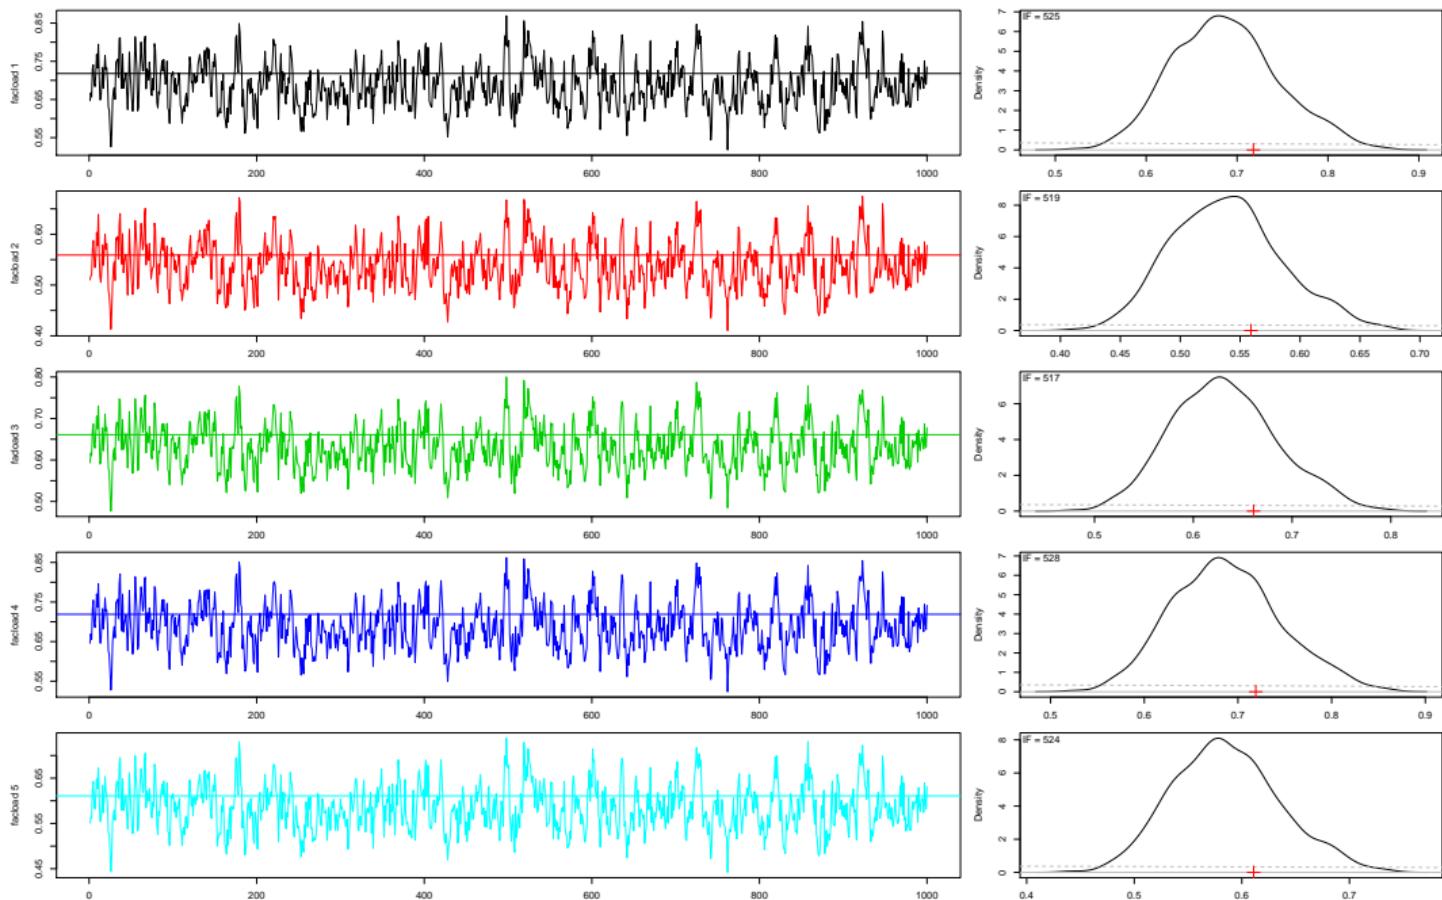

$$\mathbf{y}_t = \Lambda^* \mathbf{f}_t^* + \varepsilon_t,$$

with  $\Lambda_{ii}^* = 1$ ,  $i = 1, \dots, r$ , and

$$f_{it}^* \sim \mathcal{N}\left(0, \Lambda_{ii}^2 \cdot e^{h_{m+i,t}}\right), \quad i = 1, \dots, r,$$
$$h_{m+i,t} = \mu_{m+i} + \phi_{m+i}(h_{m+i,t} - \mu_{m+i}) + \eta_{m+i,t},$$

with  $\mu_{m+i} = 0$ .

# Shallow interweaving

## Interweaving the factor loadings

Exploit non-identifiability of factor models to move between the three levels of the hierarchical latent state representation.

Deep interweaving representation:

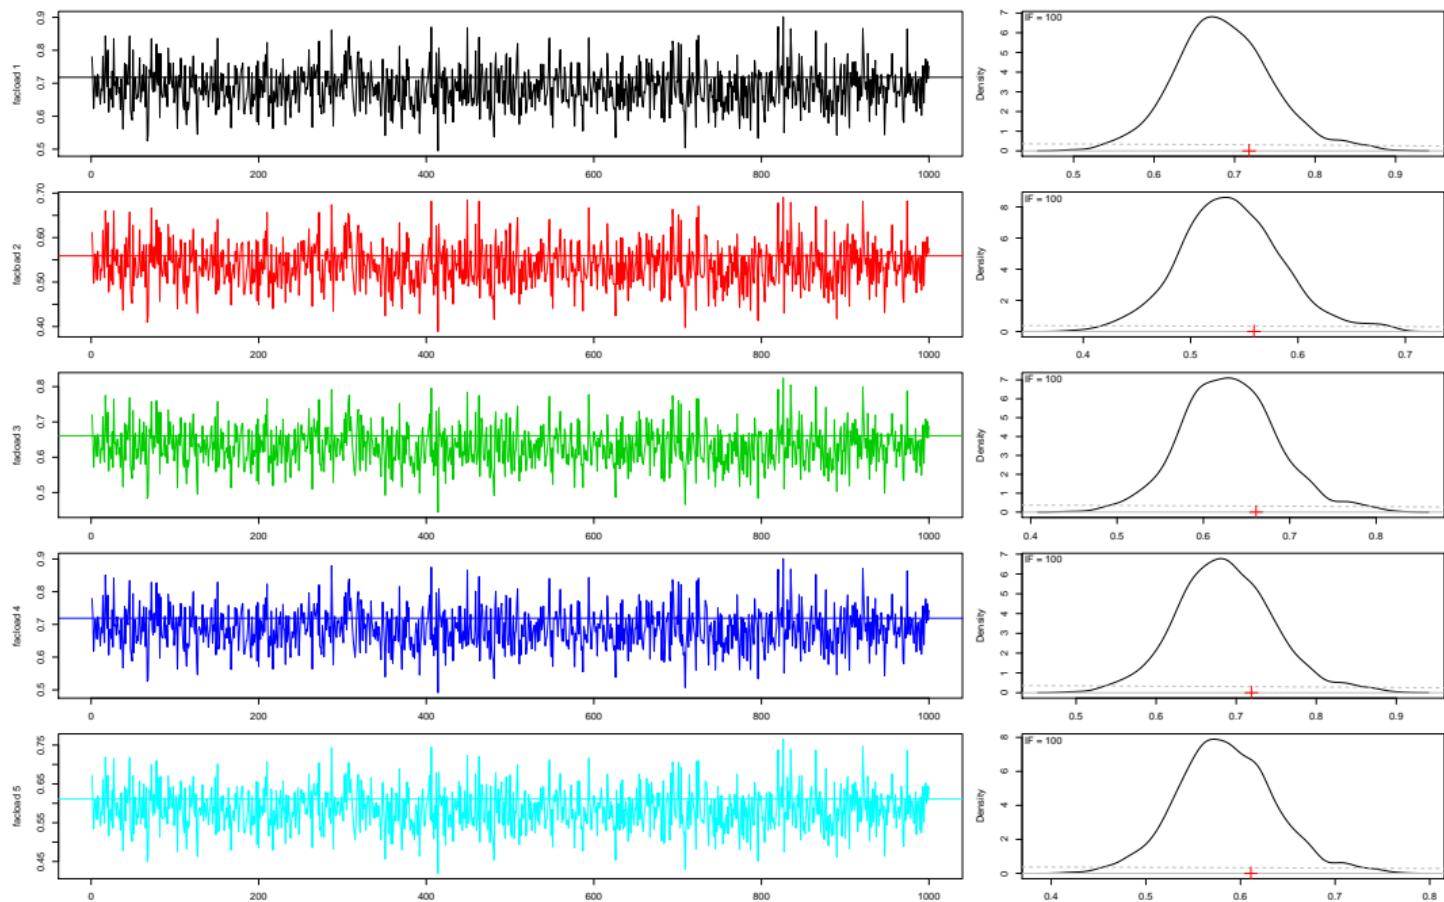

$$\mathbf{y}_t = \Lambda^* \mathbf{f}_t^* + \varepsilon_t,$$

with  $\Lambda_{ii}^* = 1$ ,  $i = 1, \dots, r$ , and

$$\begin{aligned} f_{it}^* &\sim \mathcal{N}(0, 1 \cdot e^{h_{m+i,t}}), \quad i = 1, \dots, r, \\ h_{m+i,t} &= \mu_{m+i} + \phi_{m+i}(h_{m+i,t} - \mu_{m+i}) + \eta_{m+i,t}, \end{aligned}$$

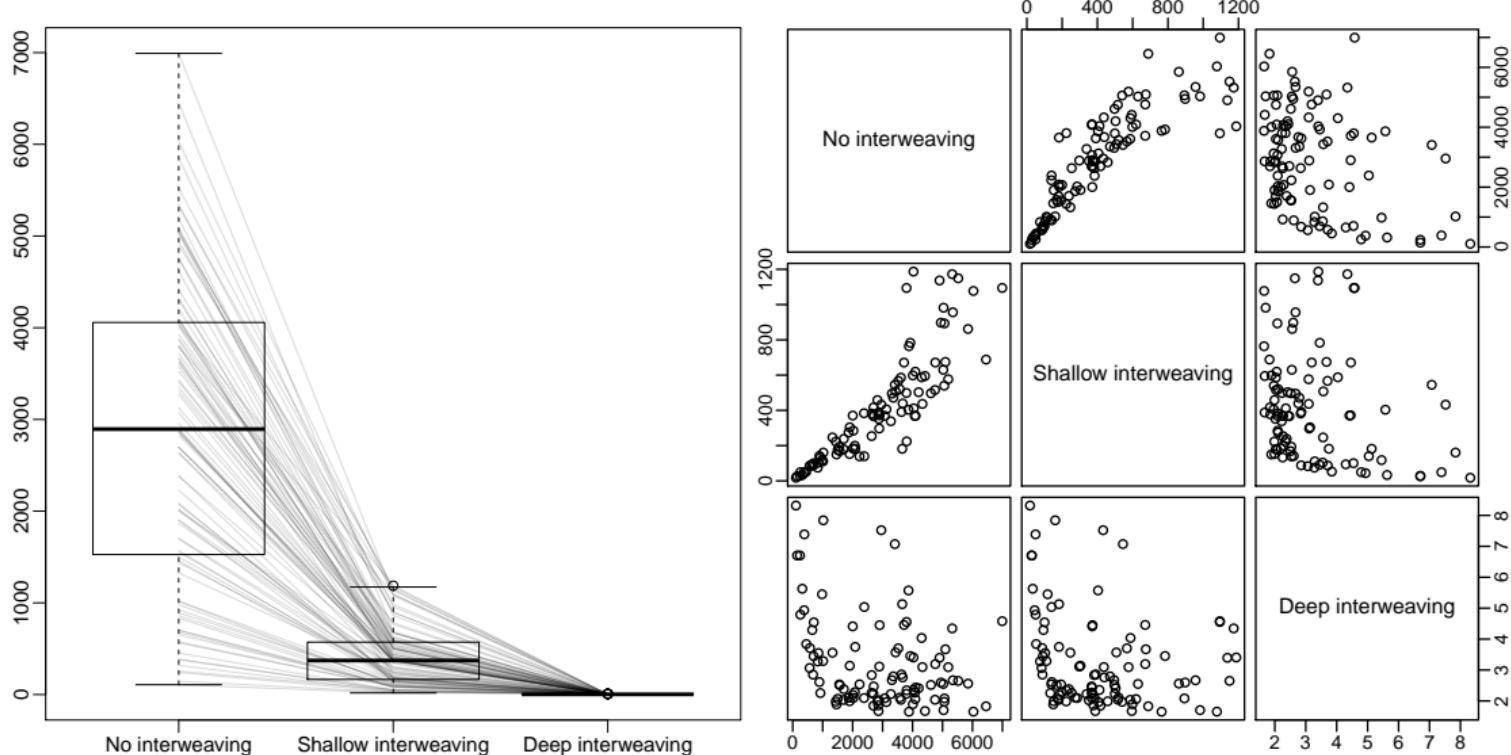

with  $\mu_{m+i} = \log \Lambda_{ii}^2$ .

# Deep interweaving

## What about sample variation?

Estimated inefficiency factors for posterior draws from  $p(\Lambda_{11}|\mathbf{y}_i)$  where  $\mathbf{y}_i, i \in \{1, \dots, 100\}$ , denote artificially generated data with identical parameters.

## Average IFs for factor loadings matrix $\Lambda$

## Some final remarks

Sparse factor SV models are...

- > a “hybrid approach” to dynamic covariance modeling, i.e. we get parsimony through
  - > factor structure, **plus additional**
  - > shrinkage
- > estimable within a fully Bayesian framework, in particular via Gibbs sampling in combination with ASIS
- > computationally doable (but by no means cheap!) in “vast dimensional” ( $T = 10000+$ ,  $m = 500+$ ,  $r = 50+$ ) applications
- > available through **R** package **factorstochvol** – almost! :)

## A Bayesian predictive framework

[Video](#)

Within a Bayesian framework, a natural way of assessing the predictive performance of a given model is through its **predictive density** (sometimes also referred to as **posterior predictive distribution**). It is given through

$$p(\mathbf{y}_{t+1}^o | \mathbf{y}_{[1:t]}^o) = \int_{\kappa} p(\mathbf{y}_{t+1}^o | \mathbf{y}_{[1:t]}^o, \kappa) \times p(\kappa | \mathbf{y}_{[1:t]}^o) d\kappa, \quad (1)$$

where  $\kappa$  denotes the vector of all unobservables, i.e., parameters and possible latent variables.

[Details](#)

## A Bayesian predictive framework

In the factor SV case, Equation 1 is a (very) high-dimensional integral which cannot be solved analytically. Nevertheless, it may be evaluated at an arbitrary point  $\mathbf{x}$  through Monte Carlo integration,

$$p(\mathbf{x}|\mathbf{y}_{[1:t]}^o) \approx \frac{1}{M} \sum_{m=1}^M p(\mathbf{x}|\mathbf{y}_{[1:t]}^o, \kappa_{[1:t]}^{(m)}), \quad (2)$$

where  $\kappa_{[1:t]}^{(m)}$  stands for the  $m^{\text{th}}$  draw from the respective posterior distribution up to time  $t$ .

If Equation 2 is evaluated at  $\mathbf{x} = \mathbf{y}_{t+1}^o$ , we refer to it as the (one-step-ahead) **predictive likelihood** at time  $t + 1$ , denoted  $PL_{t+1}$ .

Moreover, draws from the posterior predictive distribution can be obtained by simulating values  $\mathbf{y}_{t+1}^{(m)}$  from the distribution given through the density  $p(\mathbf{y}_{t+1}|\mathbf{y}_{[1:t]}^o, \kappa_{[1:t]}^{(m)})$ , the summands of Equation 2.

## A Bayesian predictive framework

It is worth pointing out that log predictive likelihoods also carry an intrinsic connection to the log **marginal likelihood**, defined through

$$\log ML = \log p(\mathbf{y}^o) = \log \int_{\kappa} p(\mathbf{y}^o | \kappa) \times p(\kappa) d\kappa.$$

This real number corresponds to the logarithm of the normalizing constant which appears in the denominator of Bayes' law and is often used for evaluating model evidence. It can straightforwardly be decomposed into the sum of the logarithms of the one-step-ahead predictive likelihoods:

$$\log ML = \log p(\mathbf{y}^o) = \log \prod_{t=1}^n p(\mathbf{y}_t^o | \mathbf{y}_{[1:t-1]}^o) = \sum_{t=1}^n \log PL_t.$$

## A Bayesian predictive framework

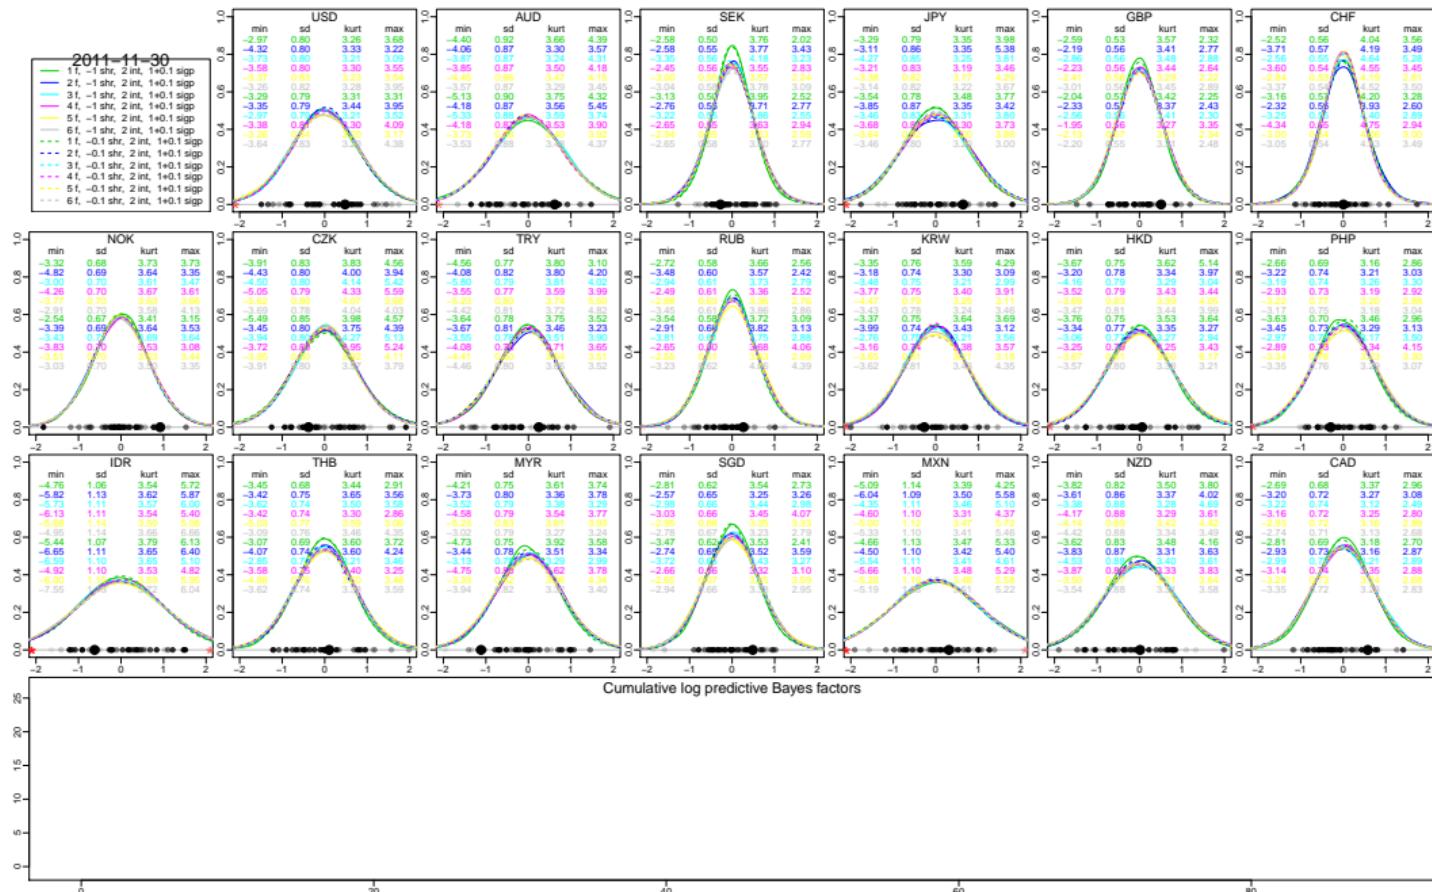

Cumulative sums of  $\log PL_t$  also allow for model comparison through cumulative log predictive Bayes factors. Letting  $PL_t(A)$  denote the predictive likelihood of model  $A$  at time  $t$ , and  $PL_t(B)$  the corresponding value of model  $B$ , the cumulative log predictive Bayes factor at time  $u$  (and starting point  $s$ ) in favor of model  $A$  over model  $B$  is straightforwardly given through

$$\log \left[ \frac{p_A(\mathbf{y}_{[s+1:u]}^o | \mathbf{y}_{[1:s]}^o)}{p_B(\mathbf{y}_{[s+1:u]}^o | \mathbf{y}_{[1:s]}^o)} \right] = \sum_{t=s+1}^u \log \left[ \frac{PL_t(A)}{PL_t(B)} \right]$$

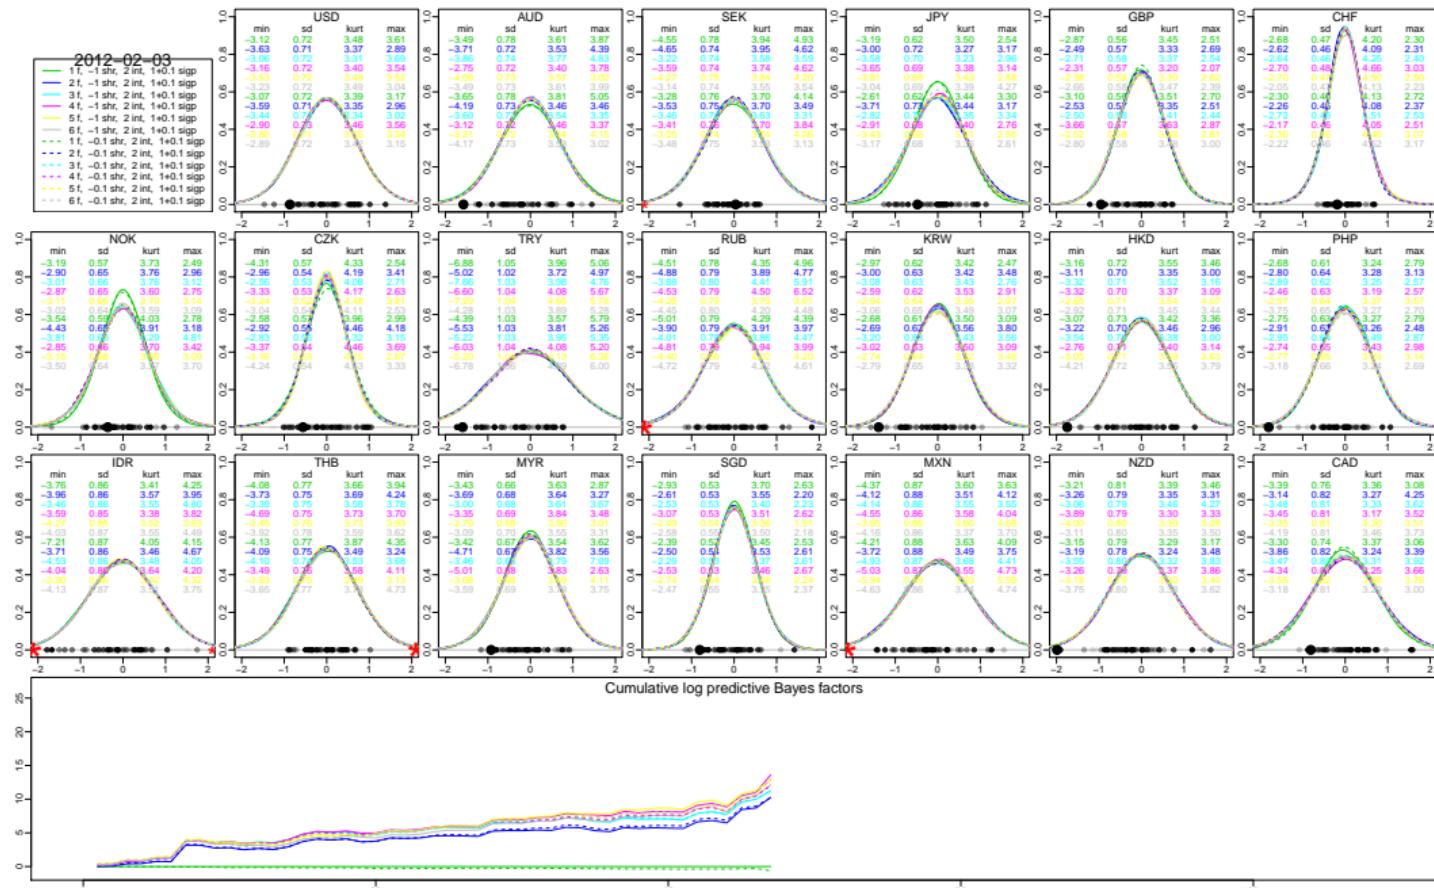

When the cumulative log predictive Bayes factor is positive at a given point in time, there is evidence in favor of model  $A$ , and vice versa. In this context, information up to time  $s$  is regarded as prior information, while out-of-sample predictive evaluation starts at time  $s + 1$ . Note that the usual (overall) log Bayes factor is a special case of this equation for  $s = 0$  and  $u = T$ . More details in Geweke and Amisano (2010), Kastner (forthcoming).

## Priors

- >  $\Lambda_{ij} \sim \mathcal{N}(0, B_\Lambda)$
- >  $\mu \sim \mathcal{N}(b_\mu, B_\mu)$
- >  $(\phi + 1)/2 \sim \mathcal{B}(a_0, b_0)$  as in Kim et al. (1998), implying

$$p(\phi) = \frac{1}{2B(a_0, b_0)} \left( \frac{1+\phi}{2} \right)^{a_0-1} \left( \frac{1-\phi}{2} \right)^{b_0-1}$$

- >  $\sigma^2 \sim B_\sigma \times \chi_1^2 = \mathcal{G}\left(\frac{1}{2}, \frac{1}{2B_\sigma}\right)$  (cf. Kastner and Frühwirth-Schnatter, 2014)
- >  $h_0 | \mu, \phi, \sigma \sim \mathcal{N}(\mu, \sigma^2 / (1 - \phi^2))$  (stationary distribution)

## Inverse Gamma prior for $\sigma^2$ ?

## Identification, applications, generalizations

For identification reasons, we (currently) set

- >  $\mu_i = 0$  for  $i \in \{m+1, \dots, m+r\}$ ,
- >  $\Lambda$  lower triangular.

⇒ (certain) order dependence among the responses!

(Selected) applications in financial econometrics:

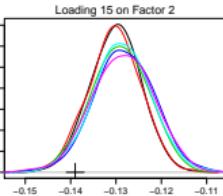

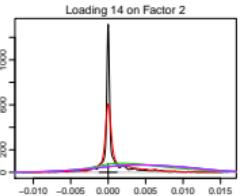

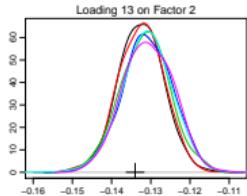

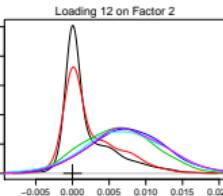

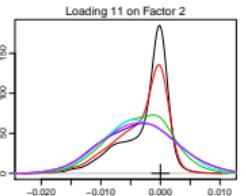

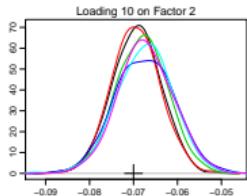

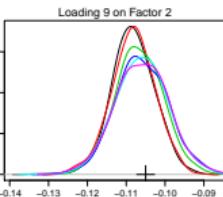

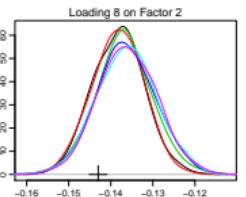

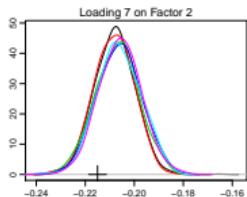

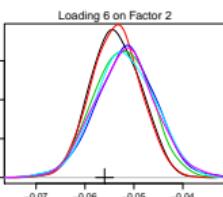

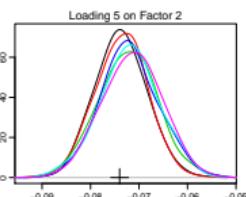

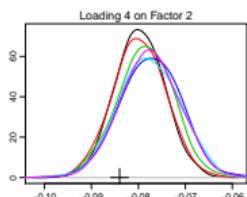

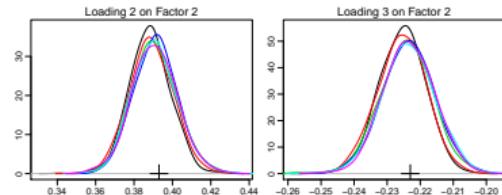

- > Asset allocation (Aguilar and West, 2000),
- > Asset pricing (Nardari and Scruggs, 2007),

extending arbitrage pricing theory (APT) and capital asset pricing models (CAPM) for time-varying covariance matrices.

Generalizations:

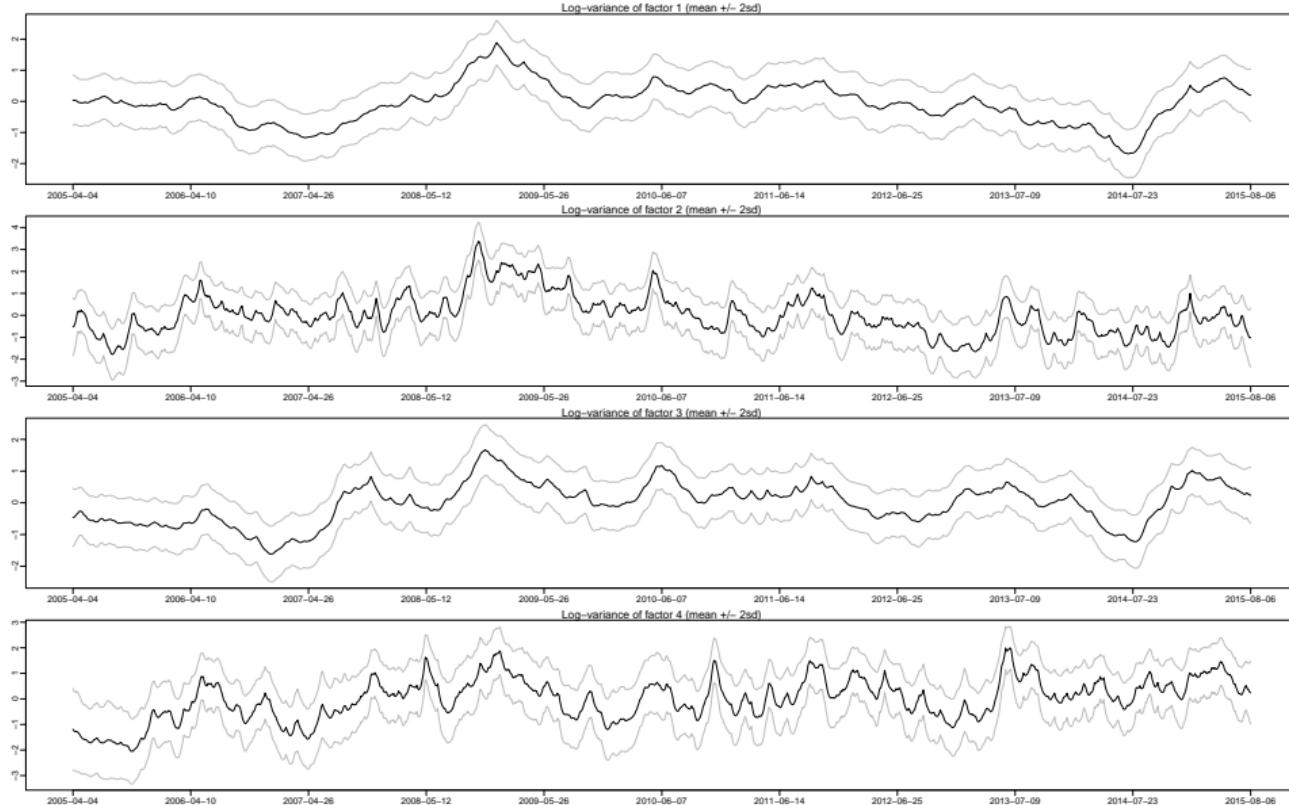

- > Time-varying loadings (Lopes and Carvalho, 2007),
- > Time-varying patterns of sparsity (Nakajima and West, 2013; Zhou et al., 2014).

- $\alpha = 0.02$
- $\alpha = 0.1$
- $\alpha = 0.46$
- $\alpha = 1.04$
- $\alpha = 5.38$
- $\alpha = 24.5$

## MCMC sampling scheme

Choose  $T(m + 2r) + mr + 4m + 3r$  starting values for  $\mu, \phi, \sigma, \mathbf{h}, \mathbf{f}, \Lambda$ , in our applications that's around around 100k or 2m, respectively. Then repeat:

- a) Perform  $m + r$  univariate SV updates for  $\mathbf{h}_i, (\mu_i), \phi_i, \sigma_i$  by using the sampler in R-package **stochvol**.
- b) Sample the factor loadings, constituting  $m$  independent  $r$ -variate regression problems with  $T$  observations.
- c) Sample the latent factors, constituting  $T$  independent  $r$ -variate regression problems with  $m$  observations.

Note that **in principle** these steps can be straightforwardly parallelized.

# Univariate SV Estimation

$\log(\varepsilon_t^2)|r_t \sim \mathcal{N}(m_{r_t}, s_{r_t}^2)$  for  $r_t \in \{1, \dots, 10\}$  (Omori et al., 2007):

1 Sample  $\mathbf{h} = (h_0, \dots, h_T)$  AWOL:

>  $\mathbf{h} = (\mathbf{L}')^{-1}(\mathbf{L}^{-1}\mathbf{c} + \boldsymbol{\varepsilon})$  with  $\Omega = \mathbf{L}\mathbf{L}'$  and  $\boldsymbol{\varepsilon} \sim \mathcal{N}_T(\mathbf{0}, \mathbf{I}_T)$

2 Sample  $\mu, \phi, \sigma$  (C):

> MH-step with independence proposal for  $(\mu, \phi) | \mathbf{h}, \sigma^2$

> MH-step with independence proposal for  $\sigma^2 | \mathbf{h}, \mu, \phi$

2\* Calculate  $\tilde{\mathbf{h}} = \frac{\mathbf{h} - \mu}{\sigma}$

2\*\* Sample  $\mu, \phi, \sigma$  (NC):

> MH-step with independence proposal for  $\phi | \tilde{\mathbf{h}}$

> Gibbs-step for  $(\mu, \sigma) | \mathbf{y}, \tilde{\mathbf{h}}, \mathbf{r}$  with possible sign switching for  $\sigma$

2\*\*\* Calculate  $\mathbf{h} = \mu + \sigma \tilde{\mathbf{h}}$  ("bookkeeping")

3 Draw indicators  $r_t$  from easily available posterior
